6.1 Function List.....	32
6.2 Mini Web Browser Interface.....	32
6.3 Exercises.....	33
6.3.1 Exercise 1.....	33
6.3.2 Exercise 2.....	33
7 Using MathRider As A Programmer's Text Editor.....	34
7.1 Creating, Opening, Saving, And Closing Text Files.....	34
7.2 Editing Files.....	34
7.3 File Modes.....	34
7.4 Learning How To Type Properly Is An Excellent Investment Of Your Time	35
7.5 Exercises.....	35
7.5.1 Exercise 1.....	35
8 MathRider Worksheet Files.....	36
8.1 Code Folds.....	36
8.1.1 The Description Attribute.....	37
8.2 Automatically Inserting Folds & Removing Unpreserved Folds.....	37
8.3 Exercises.....	38
8.3.1 Exercise 1.....	38
8.3.2 Exercise 2.....	38
8.3.3 Exercise 3.....	38
8.3.4 Exercise 4.....	38
9 MathPiper Programming Fundamentals.....	39
9.1 Values and Expressions.....	39
9.2 Operators.....	39

9.3 Operator Precedence.....	40
9.4 Changing The Order Of Operations In An Expression.....	41
9.5 Functions & Function Names.....	42
9.6 Functions That Produce Side Effects.....	43
9.6.1 Printing Related Functions: Echo(), Write(), And Newline().....	43
9.6.1.1 Echo().....	43
9.6.1.2 Echo Statements Are Useful For "Debugging" Programs.....	45
9.6.1.3 Write().....	46
9.6.1.4 NewLine().....	46
9.7 Expressions Are Separated By Semicolons.....	47
9.7.1 Placing More Than One Expression On A Line In A Fold.....	47
9.7.2 Placing More Than One Expression On A Line In The Console Using A Code Block.....	48
9.7.2.1 Automatic Bracket, Parentheses, And Brace Match Indicating....	49
9.8 Strings.....	50
9.8.1 The MathPiper Console and MathPiper Folds Can Access The Same Variables.....	51
9.8.2 Using Strings To Make Echo's Output Easier To Read.....	51
9.8.2.1 Combining Strings With The : Operator.....	51
9.8.2.2 WriteString().....	52
9.8.2.3 Nl().....	52
9.8.2.4 Space().....	52
9.8.3 Accessing The Individual Letters In A String.....	52
9.9 Comments.....	53
9.10 Exercises.....	54
9.10.1 Exercise 1.....	55
9.10.2 Exercise 2.....	55
9.10.3 Exercise 3.....	55
9.10.4 Exercise 4.....	55
9.10.5 Exercise 5.....	55
9.10.6 Exercise 6.....	56
10 Rectangular Selection Mode And Text Area Splitting.....	57
10.1 Rectangular Selection Mode.....	57
10.2 Text area splitting.....	57
11 Working With Random Integers.....	58
11.1 Obtaining Random Integers With The RandomInteger() Function.....	58
11.2 Simulating The Rolling Of Dice.....	59
12 Making Decisions.....	61
12.1 Conditional Operators.....	61
12.2 Predicate Expressions.....	64
12.3 Exercises.....	64

12.3.1 Exercise 1.....	64
12.3.2 Exercise 2.....	64
12.4 Making Decisions With The If() Function & Predicate Expressions.....	65
12.4.1 If() Functions Which Include An "Else" Parameter.....	66
12.5 Exercises.....	67
12.5.1 Exercise 1.....	67
12.6 The And(), Or(), & Not() Boolean Functions & Infix Notation.....	67
12.6.1 And().....	67
12.6.2 Or().....	68
12.6.3 Not() & Prefix Notation.....	70
12.7 Exercises.....	71
12.7.1 Exercise 1.....	71
12.7.2 Exercise 2.....	71
13 The While() Looping Function & Bodied Notation.....	73
13.1 Printing The Integers From 1 to 10.....	73
13.2 Printing The Integers From 1 to 100.....	75
13.3 Printing The Odd Integers From 1 To 99.....	75
13.4 Printing The Integers From 1 To 100 In Reverse Order.....	76
13.5 Expressions Inside Of Code Blocks Are Indented.....	77
13.6 Long-Running Loops, Infinite Loops, & Interrupting Execution.....	77
13.7 A Program That Simulates Rolling Two Dice 50 Times.....	78
13.8 Exercises.....	80
13.8.1 Exercise 1.....	80
13.8.2 Exercise 2.....	80
13.8.3 Exercise 3.....	80
14 Predicate Functions.....	81
14.1 Finding Prime Numbers With A Loop.....	82
14.2 Finding The Length Of A String With The Length() Function.....	84
14.3 Converting Numbers To Strings With The String() Function.....	85
14.4 Finding Prime Numbers Which End With 7 (And Multi-line Function Calls)	85
14.5 Exercises.....	86
14.5.1 Exercise 1.....	86
14.5.2 Exercise 2.....	87
15 Lists: Values That Hold Sequences Of Expressions.....	88
15.1 Append() & Nondestructive List Operations.....	89
15.2 Using While Loops With Lists	90
15.2.1 Using A While Loop And Append() To Place Values In A List.....	91
15.3 Exercises.....	93
15.3.1 Exercise 1.....	93
15.3.2 Exercise 2.....	93

15.3.3 Exercise 3.....	93
15.4 The ForEach() Looping Function.....	93
15.5 Print All The Values In A List Using A ForEach() function.....	93
15.6 Calculate The Sum Of The Numbers In A List Using ForEach().....	94
15.7 The .. Range Operator.....	95
15.8 Using ForEach() With The Range Operator To Print The Prime Numbers Between 1 And 100.....	96
15.8.1 Using ForEach() And The Range Operator To Place The Prime Numbers Between 1 And 50 Into A List.....	97
15.8.2 Exercises.....	98
15.8.3 Exercise 1.....	98
15.8.4 Exercise 2.....	98
15.8.5 Exercise 3.....	98
15.8.6 Exercise 4.....	98
16 Functions & Operators Which Loop Internally.....	99
16.1 Functions & Operators Which Loop Internally To Process Lists.....	99
16.1.1 TableForm().....	99
16.1.2 Contains().....	99
16.1.3 Find().....	100
16.1.4 Count().....	100
16.1.5 Select().....	101
16.1.6 The Nth() Function & The [] Operator.....	101
16.1.7 The : Prepend Operator.....	102
16.1.8 Concat().....	102
16.1.9 Insert(), Delete(), & Replace().....	102
16.1.10 Take()	103
16.1.11 Drop().....	104
16.1.12 FillList().....	104
16.1.13 RemoveDuplicates().....	105
16.1.14 Reverse().....	105
16.1.15 Partition().....	105
16.1.16 Table()	106
16.1.17 HeapSort().....	107
16.2 Functions That Work With Integers.....	107
16.2.1 RandomIntegerVector().....	107
16.2.2 Max() & Min().....	107
16.2.3 Div() & Mod().....	108
16.2.4 Gcd().....	109
16.2.5 Lcm().....	109
16.2.6 Sum().....	110
16.2.7 Product().....	110
16.3 Exercises.....	110

16.3.1 Exercise 1.....	110
16.3.2 Exercise 2.....	110
16.3.3 Exercise 3.....	111
16.3.4 Exercise 4.....	111
16.3.5 Exercise 5.....	111
17 Nested Loops.....	112
17.1 Generate All The Combinations That Can Be Entered Into A Two Digit Wheel Lock Using Two Nested Loops.....	112
17.2 Exercises.....	113
17.2.1 Exercise 1.....	113
18 User Defined Functions.....	114
18.1 Global Variables, Local Variables, & Local().....	116
18.2 Exercises.....	118
18.2.1 Exercise 1.....	118
18.2.2 Exercise 2.....	118
19 Miscellaneous topics.....	119
19.1 Incrementing And Decrementing Variables With The ++ And -- Operators	119
19.1.1 Incrementing Variables With The ++ Operator.....	119
19.1.2 Decrementing Variables With The -- Operator.....	120

1 Preface

2 1.1 Dedication

3 This book is dedicated to Steve Yegge and his blog entry "Math Every Day"
4 (<http://steve.yegge.googlepages.com/math-every-day>).

5 1.2 Acknowledgments

6 The following people have provided feedback on this book (if I forgot to include
7 your name on this list, please email me at ted.kosan at gmail.com):

8 Susan Addington

9 Matthew Moelter

10 Sherm Ostrowsky

11 1.3 Support Email List

12 The support email list for this book is called **mathrider-**
13 **users@googlegroups.com** and you can subscribe to it at
14 <http://groups.google.com/group/mathrider-users>.

15 1.4 Recommended Weekly Sequence When Teaching A Class With This 16 Book

- 17 • Week 1: Sections 1 - 6.
- 18 • Week 2: Sections 7 - 9.
- 19 • Week 3: Sections 10 - 13.
- 20 • Week 4: Sections 14 - 15.
- 21 • Week 5: Sections 16 - 19.

22 **2 Introduction**

23 MathRider is an open source mathematics computing environment for
24 performing numeric and symbolic computations (the difference between numeric
25 and symbolic computations are discussed in a later section). Mathematics
26 computing environments are complex and it takes a significant amount of time
27 and effort to become proficient at using one. The amount of power that these
28 environments make available to a user, however, is well worth the effort needed
29 to learn one. It will take a beginner a while to become an expert at using
30 MathRider, but fortunately one does not need to be a MathRider expert in order
31 to begin using it to solve problems.

32 **2.1 What Is A Mathematics Computing Environment?**

33 A Mathematics Computing Environment is a set of computer programs that 1)
34 automatically execute a wide range of numeric and symbolic mathematics
35 calculation algorithms and 2) provide a user interface which enables the user to
36 access these calculation algorithms and manipulate the mathematical objects
37 they create (An algorithm is a step-by-step sequence of instructions for solving a
38 problem and we will be learning about algorithms later in the book).

39 Standard and graphing scientific calculator users interact with these devices
40 using buttons and a small LCD display. In contrast to this, users interact with
41 MathRider using a rich graphical user interface which is driven by a computer
42 keyboard and mouse. Almost any personal computer can be used to run
43 MathRider, including the latest subnotebook computers.

44 Calculation algorithms exist for many areas of mathematics and new algorithms
45 are constantly being developed. Software that contains these kind of algorithms
46 is commonly referred to as "Computer Algebra Systems (CAS)". A significant
47 number of computer algebra systems have been created since the 1960s and the
48 following list contains some of the more popular ones:

49 http://en.wikipedia.org/wiki/Comparison_of_computer_algebra_systems

50 Some environments are highly specialized and some are general purpose. Some
51 allow mathematics to be entered and displayed in traditional form (which is what
52 is found in most math textbooks). Some are able to display traditional form
53 mathematics but need to have it input as text and some are only able to have
54 mathematics displayed and entered as text.

55 As an example of the difference between traditional mathematics form and text
56 form, here is a formula which is displayed in traditional form:

$$a = x^2 + 4hx + \frac{3}{7}$$

57 and here is the same formula in text form:

58
$$a = x^2 + 4 \cdot h \cdot x + 3/7$$

59 Most computer algebra systems contain a mathematics-oriented programming
60 language. This allows programs to be developed which have access to the
61 mathematics algorithms which are included in the system. Some mathematics-
62 oriented programming languages were created specifically for the system they
63 work in while others were built on top of an existing programming language.

64 Some mathematics computing environments are proprietary and need to be
65 purchased while others are open source and available for free. Both kinds of
66 systems possess similar core capabilities, but they usually differ in other areas.

67 Proprietary systems tend to be more polished than open source systems and they
68 often have graphical user interfaces that make inputting and manipulating
69 mathematics in traditional form relatively easy. However, proprietary
70 environments also have drawbacks. One drawback is that there is always a
71 chance that the company that owns it may go out of business and this may make
72 the environment unavailable for further use. Another drawback is that users are
73 unable to enhance a proprietary environment because the environment's source
74 code is not made available to users.

75 Some open source computer algebra systems do not have graphical user
76 interfaces, but their user interfaces are adequate for most purposes and the
77 environment's source code will always be available to whomever wants it. This
78 means that people can use the environment for as long as they desire and they
79 can also enhance it.

80 **2.2 What Is MathRider?**

81 MathRider is an open source Mathematics Computing Environment which has
82 been designed to help people teach themselves the [STEM](#) disciplines (Science,
83 Technology, Engineering, and Mathematics) in an efficient and holistic way. It
84 inputs mathematics in textual form and displays it in either textual form or
85 traditional form.

86 MathRider uses MathPiper as its default computer algebra system, BeanShell as
87 its main scripting language, jEdit as its framework (hereafter referred to as the
88 MathRider framework), and Java as its overall implementation language. One
89 way to determine a person's MathRider expertise is by their knowledge of these
90 components. (see Table 1)

Level	Knowledge
MathRider Developer	Knows Java, BeanShell, and the MathRider framework at an advanced level. Is able to develop MathRider plugins.
MathRider Customizer	Knows Java, BeanShell, and the MathRider framework at an intermediate level. Is able to develop MathRider macros.
MathRider Expert	Knows MathPiper at an advanced level and is skilled at using most aspects of the MathRider application.
MathRider Novice	Knows MathPiper at an intermediate level, but has only used MathRider for a short while.
MathRider Newbie	Does not know MathPiper but has been exposed to at least one programming language.
Programming Newbie	Does not know how a computer works and has never programmed before but knows how to use a word processor.

Table 1: MathRider user experience levels.

91 This book is for MathRider and Programming Newbies. This book will teach you
 92 enough programming to begin solving problems with MathRider and the
 93 language that is used is MathPiper. It will help you to become a MathRider
 94 Novice, but you will need to learn MathPiper from books that are dedicated to it
 95 before you can become a MathRider Expert.

96 The MathRider project website (<http://mathrider.org>) contains more information
 97 about MathRider along with other MathRider resources.

98 **2.3 What Inspired The Creation Of Mathrider?**

99 Two of MathRider's main inspirations are Scott McNeally's concept of "No child
 100 held back":

101 http://weblogs.java.net/blog/turbogeek/archive/2004/09/no_child_held_b_1.html

102 and Steve Yegge's thoughts on learning mathematics:

103 1) Math is a lot easier to pick up after you know how to program. In fact, if
 104 you're a halfway decent programmer, you'll find it's almost a snap.

105 2) They teach math all wrong in school. Way, WAY wrong. If you teach
 106 yourself math the right way, you'll learn faster, remember it longer, and it'll
 107 be much more valuable to you as a programmer.

108 3) The right way to learn math is breadth-first, not depth-first. You need to
 109 survey the space, learn the names of things, figure out what's what.

110 <http://steve-yegge.blogspot.com/2006/03/math-for-programmers.html>

111 MathRider is designed to help a person learn mathematics on their own with
112 little or no assistance from a teacher. It makes learning mathematics easier by
113 focusing on how to program first and it facilitates a breadth-first approach to
114 learning mathematics.

115 **3 Downloading And Installing MathRider**

116 **3.1 *Installing Sun's Java Implementation***

117 MathRider is a Java-based application and therefore a current version of Sun's
118 Java (at least Java 6) must be installed on your computer before MathRider can
119 be run.

120 **3.1.1 Installing Java On A Windows PC**

121 Many Windows PCs will already have a current version of Java installed. You can
122 test to see if you have a current version of Java installed by visiting the following
123 web site:

124 <http://java.com/>

125 This web page contains a link called "Do I have Java?" which will check your Java
126 version and tell you how to update it if necessary.

127 **3.1.2 Installing Java On A Macintosh**

128 Macintosh computers have Java pre-installed but you may need to upgrade to a
129 current version of Java (at least Java 6) before running MathRider. If you need
130 to update your version of Java, visit the following website:

131 <http://developer.apple.com/java.>

132 **3.1.3 Installing Java On A Linux PC**

133 Locate the Java documentation for your Linux distribution and carefully follow
134 the instructions provided for installing a Java 6 compatible version of Java on
135 your system.

136 **3.2 *Downloading And Extracting***

137 One of the many benefits of learning MathRider is the programming-related
138 knowledge one gains about how open source software is developed on the
139 Internet. An important enabler of open source software development are
140 websites, such as sourceforge.net (<http://sourceforge.net>) and java.net
141 (<http://java.net>) which make software development tools available for free to
142 open source developers.

143 MathRider is hosted at java.net and the URL for the project website is:

144 <http://mathrider.org>

145 MathRider can be obtained by selecting the **download** tab and choosing the
146 correct download file for your computer. Place the download file on your hard
147 drive where you want MathRider to be located. **For Windows users, it is**
148 **recommended that MathRider be placed somewhere on c: drive.**

149 The MathRider download consists of a main directory (or folder) called
150 **mathrider** which contains a number of directories and files. In order to make
151 downloading quicker and sharing easier, the mathrider directory (and all of its
152 contents) have been placed into a single compressed file called an **archive**. For
153 **Windows** systems, the archive has a **.zip** extension and the archives for **Unix-**
154 **based** systems have a **.tar.bz2** extension.

155 After an archive has been downloaded onto your computer, the directories and
156 files it contains must be **extracted** from it. The process of extraction
157 uncompresses copies of the directories and files that are in the archive and
158 places them on the hard drive, usually in the same directory as the archive file.
159 After the extraction process is complete, the archive file will still be present on
160 your drive along with the extracted **mathrider** directory and its contents.

161 The **archive file** can be easily copied to a CD or USB drive if you would like to
162 install MathRider on another computer or give it to a friend. **However, don't**
163 **try to run MathRider from a USB drive because it will not work correctly.**

164 **(Note: If you already have a version of MathRider installed and you want**
165 **to install a new version in the same directory that holds the old version,**
166 **you must delete the old version first or move it to a separate directory.)**

167 3.2.1 Extracting The Archive File For Windows Users

168 Usually the easiest way for Windows users to extract the MathRider archive file
169 is to navigate to the folder which contains the archive file (using the Windows
170 GUI), **right click on the archive file (it should appear as a folder with a**
171 **vertical zipper on it)**, and select **Extract All...** from the pop up menu.

172 After the extraction process is complete, a new folder called **mathrider** should
173 be present in the same folder that contains the archive file. **(Note: be careful**
174 **not to double click on the archive file by mistake when you are trying to**
175 **open the mathrider folder. The Windows operating system will open the**
176 **archive just like it opens folders and this can fool you into thinking you**
177 **are opening the mathrider folder when you are not. You may want to**
178 **move the archive file to another place on your hard drive after it has**
179 **been extracted to avoid this potential confusion.)**

180 3.2.2 Extracting The Archive File For Unix Users

181 One way Unix users can extract the download file is to open a shell, change to
182 the directory that contains the archive file, and extract it using the following
183 command:

184 tar -xvjf <name of archive file>

185 If your desktop environment has GUI-based archive extraction tools, you can use
186 these as an alternative.

187 **3.3 MathRider's Directory Structure & Execution Instructions**

188 The top level of MathRider's directory structure is shown in Illustration 1:

Illustration 1: MathRider's Directory Structure

189 The following is a brief description this top level directory structure:

190 **doc** - Contains MathRider's documentation files.

191 **examples** - Contains various example programs, some of which are pre-opened
192 when MathRider is first executed.

193 **jars** - Holds plugins, code libraries, and support scripts.

194 **macros** - Contains various scripts that can be executed by the user.

195 **modes** - Contains files which tell MathRider how to do syntax highlighting for
196 various file types.

197 **settings** - Contains the application's main settings files.

198 **startup** - Contains startup scripts that are executed each time MathRider
199 launches.

200 **jedit.jar** - Holds the core jEdit application which MathRider builds upon.

201 **unix_run.sh** - The script used to execute MathRider on Unix systems.

202 **win_run.bat** - The batch file used to execute MathRider on Windows systems.

203 **3.3.1 Executing MathRider On Windows Systems**

204 Open the **mathrider** folder **(not the archive file!)** and double click on the
205 **win_run** file.

206 **3.3.2 Executing MathRider On Unix Systems**

207 Open a shell, change to the **mathrider** folder, and execute the **unix_run.sh**
208 script by typing the following:

```
209     sh unix_run.sh
```

210 **3.3.2.1 MacOS X**

211 Make a note of where you put the Mathrider application (for example
212 **/Applications/mathrider**). Run Terminal (which is in /Applications/Utilities).
213 Change to that directory (folder) by typing:

```
214     cd /Applications/mathrider
```

215 Run mathrider by typing:

```
216     sh unix_run.sh
```

217 4 The Graphical User Interface

218 MathRider is built on top of jEdit (<http://jedit.org>) so it has the "heart" of a
219 programmer's text editor. Programmer's text editors are similar to standard text
220 editors (like NotePad and WordPad) and word processors (like MS Word and
221 OpenOffice) in a number of ways so getting started with MathRider should be
222 relatively easy for anyone who has used a text editor or a word processor.
223 However, programmer's text editors are more challenging to use than a standard
224 text editor or a word processor because programmer's text editors have
225 capabilities that are far more advanced than these two types of applications.

226 Most software is developed with a programmer's text editor (or environments
227 which contain one) and so learning how to use a programmer's text editor is one
228 of the many skills that MathRider provides which can be used in other areas.
229 The MathRider series of books are designed so that these capabilities are
230 revealed to the reader over time.

231 In the following sections, the main parts of MathRider's graphical user interface
232 are briefly covered. Some of these parts are covered in more depth later in the
233 book and some are covered in other books.

234 **As you read through the following sections, I encourage you to explore**
235 **each part of MathRider that is being discussed using your own copy of**
236 **MathRider.**

237 4.1 Buffers And Text Areas

238 In MathRider, open files are called **buffers** and they are viewed through one or
239 more **text areas**. Each text area has a tab at its upper-left corner which displays
240 the name of the buffer it is working on along with an indicator which shows
241 whether the buffer has been saved or not. The user is able to select a text area
242 by clicking its tab and double clicking on the tab will close the text area. Tabs
243 can also be rearranged by dragging them to a new position with the mouse.

244 4.2 The Gutter

245 The gutter is the vertical gray area that is on the left side of the main window. It
246 can contain line numbers, buffer manipulation controls, and context-dependent
247 information about the text in the buffer.

248 4.3 Menus

249 The main menu bar is at the top of the application and it provides access to a
250 significant portion of MathRider's capabilities. The commands (or **actions**) in
251 these menus all exist separately from the menus themselves and they can be
252 executed in alternate ways (such as keyboard shortcuts). The menu items (and

253 even the menus themselves) can all be customized, but the following sections
254 describe the default configuration.

255 4.3.1 File

256 The File menu contains actions which are typically found in normal text editors
257 and word processors. The actions to create new files, save files, and open
258 existing files are all present along with variations on these actions.

259 Actions for opening recent files, configuring the page setup, and printing are
260 also present.

261 4.3.2 Edit

262 The Edit menu also contains actions which are typically found in normal text
263 editors and word processors (such as **Undo**, **Redo**, **Cut**, **Copy**, and **Paste**).
264 However, there are also a number of more sophisticated actions available which
265 are of use to programmers. For beginners, though, the typical actions will be
266 sufficient for most editing needs.

267 4.3.3 Search

268 The actions in the Search menu are used heavily, even by beginners. A good way
269 to get your mind around the search actions is to open the Search dialog window
270 by selecting the **Find...** action (which is the first actions in the Search menu). A
271 **Search And Replace** dialog window will then appear which contains access to
272 most of the search actions.

273 At the top of this dialog window is a text area labeled **Search for** which allows
274 the user to enter text they would like to find. Immediately below it is a text area
275 labeled **Replace with** which is for entering optional text that can be used to
276 replace text which is found during a search.

277 The column of radio buttons labeled **Search in** allows the user to search in a
278 **Selection** of text (which is text which has been highlighted), the **Current**
279 **Buffer** (which is the one that is currently active), **All buffers** (which means all
280 opened files), or a whole **Directory** of files. The default is for a search to be
281 conducted in the current buffer and this is the mode that is used most often.

282 The column of check boxes labeled **Settings** allows the user to either **Keep or**
283 **hide the Search dialog window** after a search is performed, **Ignore the case**
284 of searched text, use an advanced search technique called a **Regular**
285 **expression** search (which is covered in another book), and to perform a
286 **HyperSearch** (which collects multiple search results in a text area).

287 The **Find** button performs a normal find operation. **Replace & Find** will replace
288 the previously found text with the contents of the **Replace with** text area and
289 perform another find operation. **Replace All** will find all occurrences of the

290 contents of the **Search for** text area and replace them with the contents of the
291 **Replace with** text area.

292 **4.3.4 Markers, Folding, and View**

293 These are advanced menus and they are described in later sections.

294 **4.3.5 Utilities**

295 The utilities menu contains a significant number of actions, some that are useful
296 to beginners and others that are meant for experts. The two actions that are
297 most useful to beginners are the **Buffer Options** actions and the **Global**
298 **Options** actions. The **Buffer Options** actions allows the currently selected
299 buffer to be customized and the **Global Options** actions brings up a rich dialog
300 window that allows numerous aspects of the MathRider application to be
301 configured.

302 Feel free to explore these two actions in order to learn more about what they do.

303 **4.3.6 Macros**

304 This is an advanced menu and it is described in a later sections.

305 **4.3.7 Plugins**

306 Plugins are component-like pieces of software that are designed to provide an
307 application with extended capabilities and they are similar in concept to physical
308 world components. The tabs on the right side of the application which are
309 labeled "GeoGebra", "Jung", "MathPiper", "MathPiperDocs", etc. are all plugins
310 and they can be **opened** and **closed** by clicking on their **tabs**. **Feel free to close**
311 **any of these plugins which may be opened if you are not currently using**
312 **them**. MathRider pPlugins are covered in more depth in a later section.

313 **4.3.8 Help**

314 The most important action in the **Help** menu is the **MathRider Help** action.
315 This action brings up a dialog window with contains documentation for the core
316 MathRider application along with documentation for each installed plugin.

317 **4.4 The Toolbar**

318 The **Toolbar** is located just beneath the menus near the top of the main window
319 and it contains a number of icon-based buttons. These buttons allow the user to
320 access the same actions which are accessible through the menus just by clicking
321 on them. There is not room on the toolbar for all the actions in the menus to be

322 displayed, but the most common actions are present. The user also has the
323 option of customizing the toolbar by using the **Utilities->Global Options->Tool**
324 **Bar** dialog.

325 **4.4.1 Undo And Redo**

326 The **Undo** button on the toolbar is able to undo any text was entered since the
327 current session of MathRider was launched. This is very handy for undoing
328 mistakes or getting back text which was deleted. The **Redo** button can be used
329 if you have selected Undo too many times and you need to "undo" one ore more
330 Undo operations.

331 **5 MathPiper: A Computer Algebra System For Beginners**

332 Computer algebra systems are extremely powerful and very useful for solving
333 STEM-related problems. In fact, one of the reasons for creating MathRider was
334 to provide a vehicle for delivering a computer algebra system to as many people
335 as possible. If you like using a scientific calculator, you should love using a
336 computer algebra system!

337 At this point you may be asking yourself "if computer algebra systems are so
338 wonderful, why aren't more people using them?" One reason is that most
339 computer algebra systems are complex and difficult to learn. Another reason is
340 that proprietary systems are very expensive and therefore beyond the reach of
341 most people. Luckily, there are some open source computer algebra systems
342 that are powerful enough to keep most people engaged for years, and yet simple
343 enough that even a beginner can start using them. MathPiper (which is based on
344 a CAS called Yacas) is one of these simpler computer algebra systems and it is
345 the computer algebra system which is included by default with MathRider.

346 A significant part of this book is devoted to learning MathPiper and a good way
347 to start is by discussing the difference between numeric and symbolic
348 computations.

349 **5.1 Numeric Vs. Symbolic Computations**

350 A Computer Algebra System (CAS) is software which is capable of performing
351 both **numeric** and **symbolic** computations. **Numeric** computations are
352 performed exclusively with numerals and these are the type of computations that
353 are performed by typical hand-held calculators.

354 **Symbolic** computations (which also called algebraic computations) relate "...to
355 the use of machines, such as computers, to manipulate mathematical equations
356 and expressions in symbolic form, as opposed to manipulating the
357 approximations of specific numerical quantities represented by those symbols."
358 (http://en.wikipedia.org/wiki/Symbolic_mathematics).

359 Since most people who read this document will probably be familiar with
360 performing numeric calculations as done on a scientific calculator, the next
361 section shows how to use MathPiper as a scientific calculator. The section after
362 that then shows how to use MathPiper as a symbolic calculator. Both sections
363 use the console interface to MathPiper. In MathRider, a console interface to any
364 plugin or application is a text-only **shell** or **command line** interface to it. This
365 means that you type on the keyboard to send information to the console and it
366 prints text to send you information.

367 **5.2 Using The MathPiper Console As A Numeric (Scientific) Calculator**

368 Open the MathPiper plugin by selecting the **MathPiper** tab in the lower left part
369 of the MathRider application. The MathPiper **console** interface is a text area
370 which is inside this plugin. Feel free to increase or decrease the size of the
371 console text area if you would like by dragging on the dotted lines which are at
372 the top side and right side of the console window.

373 When the MathPiper console is first launched, it prints a welcome message and
374 then provides **In>** as an input prompt:

```
375 MathPiper version ".76x".
```

```
376 In>
```

377 Click to the right of the prompt in order to place the cursor there then type **2+2**
378 followed by **<shift><enter>** (or **<shift><return>** on a Macintosh):

```
379 In> 2+2
```

```
380 Result> 4
```

```
381 In>
```

382 When **<shift><enter>** was pressed, 2+2 was read into MathPiper for
383 **evaluation** and **Result>** was printed followed by the result **4**. Another input
384 prompt was then displayed so that further input could be entered. This **input,**
385 **evaluation, output** process will continue as long as the console is running and
386 it is sometimes called a **Read, Eval, Print Loop** or **REPL**. In further examples,
387 the last **In>** prompt will not be shown to save space.

388 In addition to addition, MathPiper can also do subtraction, multiplication,
389 exponents, and division:

```
390 In> 5-2
```

```
391 Result> 3
```

```
392 In> 3*4
```

```
393 Result> 12
```

```
394 In> 2^3
```

```
395 Result> 8
```

```
396 In> 12/6
```

```
397 Result> 2
```

398 Notice that the multiplication symbol is an asterisk (*), the exponent symbol is a
399 caret (^), and the division symbol is a forward slash (/). These symbols (along
400 with addition (+), subtraction (-), and ones we will talk about later) are called

401 **operators** because they tell MathPiper to perform an operation such as addition
402 or division.

403 MathPiper can also work with decimal numbers:

```
404 In> .5+1.2  
405 Result> 1.7
```

```
406 In> 3.7-2.6  
407 Result> 1.1
```

```
408 In> 2.2*3.9  
409 Result> 8.58
```

```
410 In> 2.2^3  
411 Result> 10.648
```

```
412 In> 9.5/3.2  
413 Result> 9.5/3.2
```

414 In the last example, MathPiper returned the fraction unevaluated. This
415 sometimes happens due to MathPiper's symbolic nature, but a result in **numeric**
416 **form** can be obtained by using the **N()** function:

```
417 In> N(9.5/3.2)  
418 Result> 2.96875
```

419 As can be seen here, when a result is given in numeric form, it means that it is
420 given as a decimal number. The **N()** function is discussed in the next section.

421 5.2.1 Functions

422 **N()** is an example of a **function**. A function can be thought of as a "black box"
423 which accepts input, processes the input, and returns a result. Each function
424 has a name and in this case, the name of the function is **N** which stands for
425 "**numeric**". To the right of a function's name there is always a set of
426 parentheses and information that is sent to the function is placed inside of them.
427 The purpose of the **N()** function is to make sure that the information that is sent
428 to it is processed numerically instead of symbolically.

429 5.2.1.1 The Sqrt() Square Root Function

430 The following example show the **N()** function being used with the square root
431 function **Sqrt()**:

```
432 In> Sqrt(9)  
433 Result: 3
```

```
434 In> Sqrt(8)
435 Result: Sqrt(8)
```

```
436 In> N(Sqrt(8))
437 Result: 2.828427125
```

438 Notice that Sqrt(9) returned 3 as expected but Sqrt(8) returned Sqrt(8). We
439 needed to use the N() function to force the square root function to return a
440 numeric result. The reason that Sqrt(8) does not appear to have done anything
441 is because computer algebra systems like to work with expressions that are as
442 exact as possible. In this case the **symbolic** value Sqrt(8) represents the number
443 that is the square root of 8 more accurately than any decimal number can.

444 For example, the following four decimal numbers all represent $\sqrt{8}$, but none of
445 them represent it more accurately than Sqrt(8) does:

```
446 2.828427125
```

```
447 2.82842712474619
```

```
448 2.82842712474619009760337744842
```

```
449 2.8284271247461900976033774484193961571393437507539
```

450 Whenever MathPiper returns a symbolic result and a numeric result is desired,
451 simply use the N() function to obtain one. The ability to work with symbolic
452 values are one of the things that make computer algebra systems so powerful
453 and they are discussed in more depth in later sections.

454 **5.2.1.2 The IsEven() Function**

455 Another often used function is **IsEven()**. The **IsEven()** function takes a number
456 as input and returns **True** if the number is even and **False** if it is not even:

```
457 In> IsEven(4)
458 Result> True
```

```
459 In> IsEven(5)
460 Result> False
```

461 MathPiper has a large number of functions some of which are described in more
462 depth in the MathPiper Documentation section and the MathPiper Programming
463 Fundamentals section. **A complete list of MathPiper's functions is**
464 **contained in the MathPiperDocs plugin and more of these functions will**
465 **be discussed soon.**

466 **5.2.2 Accessing Previous Input And Results**

467 The MathPiper console is like a mini text editor which means you can copy text

468 from it, paste text into it, and edit existing text. You can also reevaluate previous
469 input by simply placing the cursor on the desired **In>** line and pressing
470 **<shift><enter>** on it again.

471 The console also keeps a history of all input lines that have been evaluated. If
472 the cursor is placed on any **In>** line, pressing **<ctrl><up arrow>** will display
473 each previous line of input that has been entered.

474 Finally, MathPiper associates the most recent computation result with the
475 percent (%) character. If you want to use the most recent result in a new
476 calculation, access it with this character:

```
477 In> 5*8
478 Result> 40
```

```
479 In> %
480 Result> 40
```

```
481 In> %*2
482 Result> 80
```

483 **5.3 Saving And Restoring A Console Session**

484 If you need to save the contents of a console session, you can copy and paste it
485 into a MathRider buffer and then save the buffer. You can also copy a console
486 session out of a previously saved buffer and paste it into the console for further
487 processing. Section 7 **Using MathRider As A Programmer's Text Editor**
488 discusses how to use the text editor that is built into MathRider.

489 **5.3.1 Syntax Errors**

490 An expression's **syntax** is related to whether it is **typed** correctly or not. If input
491 is sent to MathPiper which has one or more typing errors in it, MathPiper will
492 return an error message which is meant to be helpful for locating the error. For
493 example, if a backwards slash (\) is entered for division instead of a forward slash
494 (/), MathPiper returns the following error message:

```
495 In> 12 \ 6
496 Error parsing expression, near token \
```

497 The easiest way to fix this problem is to press the **up arrow** key to display the
498 previously entered line in the console, change the \ to a /, and reevaluate the
499 expression.

500 This section provided a short introduction to using MathPiper as a numeric
501 calculator and the next section contains a short introduction to using MathPiper
502 as a symbolic calculator.

503 **5.4 Using The MathPiper Console As A Symbolic Calculator**

504 MathPiper is good at numeric computation, but it is great at symbolic
505 computation. If you have never used a system that can do symbolic computation,
506 you are in for a treat!

507 As a first example, lets try adding fractions (which are also called **rational**
508 **numbers**). Add $\frac{1}{2} + \frac{1}{3}$ in the MathPiper console:

```
509 In> 1/2 + 1/3  
510 Result> 5/6
```

511 Instead of returning a numeric result like 0.83333333333333333333 (which is
512 what a scientific calculator would return) MathPiper added these two rational
513 numbers symbolically and returned $\frac{5}{6}$. If you want to work with this result
514 further, remember that it has also been stored in the % symbol:

```
515 In> %  
516 Result> 5/6
```

517 Lets say that you would like to have MathPiper determine the numerator of this
518 result. This can be done by using (or **calling**) the **Numerator()** function:

```
519 In> Numerator(%)  
520 Result> 5
```

521 Unfortunately, the % symbol cannot be used to have MathPiper determine the
522 denominator of $\frac{5}{6}$ because it only holds the result of the most recent
523 calculation and $\frac{5}{6}$ was calculated two steps back.

524 **5.4.1 Variables**

525 What would be nice is if MathPiper provided a way to store **results** (which are
526 also called **values**) in symbols that we choose instead of ones that it chooses.
527 Fortunately, this is exactly what it does! Symbols that can be associated with
528 values are called **variables**. Variable names must start with an upper or lower
529 case letter and be followed by zero or more upper case letters, lower case
530 letters, or numbers. Examples of variable names include: 'a', 'b', 'x', 'y', 'answer',
531 'totalAmount', and 'loop6'.

532 The process of associating a value with a variable is called **assigning** or **binding**
533 the value to the variable and this consists of placing the name of a variable you

would like to create on the left side of an assignment operator (`:=`) and an expression on the right side of this operator. When the expression returns a value, the value is assigned (or bound to) to the variable.

Lets recalculate $\frac{1}{2} + \frac{1}{3}$ but this time we will assign the result to the variable 'a':

```
In> a := 1/2 + 1/3
Result> 5/6
```

```
In> a
Result> 5/6
```

```
In> Numerator(a)
Result> 5
```

```
In> Denominator(a)
Result> 6
```

In this example, the assignment operator (`:=`) was used to assign the result (or **value**) $\frac{5}{6}$ to the variable 'a'. **When 'a' was evaluated by itself, the value it was bound to (in this case $\frac{5}{6}$) was returned.** This value will stay bound to the variable 'a' as long as MathPiper is running unless 'a' is cleared with the **Clear()** function or 'a' has another value assigned to it. This is why we were able to determine both the numerator and the denominator of the rational number assigned to 'a' using two functions in turn.

5.4.1.1 Calculating With Unbound Variables

Here is an example which shows another value being assigned to 'a':

```
In> a := 9
Result> 9
```

```
In> a
Result> 9
```

and the following example shows 'a' being cleared (or **unbound**) with the **Clear()** function:

```
In> Clear(a)
Result> True
```

```
In> a
Result> a
```

565 Notice that the `Clear()` function returns '**True**' as a result after it is finished to
566 indicate that the variable that was sent to it was successfully cleared (or
567 **unbound**). Many functions either return '**True**' or '**False**' to indicate whether or
568 not the operation they performed succeeded. Also notice that unbound variables
569 return themselves when they are evaluated. In this case, 'a' returned 'a'.

570 **Unbound variables** may not appear to be very useful, but they provide the
571 flexibility needed for computer algebra systems to perform symbolic calculations.
572 In order to demonstrate this flexibility, let's first factor some numbers using the
573 **Factor()** function:

```
574 In> Factor(8)
575 Result> 2^3
```

```
576 In> Factor(14)
577 Result> 2*7
```

```
578 In> Factor(2343)
579 Result> 3*11*71
```

580 Now let's factor an expression that contains the unbound variable 'x':

```
581 In> x
582 Result> x
```

```
583 In> IsBound(x)
584 Result> False
```

```
585 In> Factor(x^2 + 24*x + 80)
586 Result> (x+20)*(x+4)
```

```
587 In> Expand(%)
588 Result> x^2+24*x+80
```

589 Evaluating 'x' by itself shows that it does not have a value bound to it and this
590 can also be determined by passing 'x' to the **IsBound()** function. `IsBound()`
591 returns '**True**' if a variable is bound to a value and '**False**' if it is not.

592 What is more interesting, however, are the results returned by **Factor()** and
593 **Expand()**. **Factor()** is able to determine when expressions with unbound
594 variables are sent to it and it uses the rules of algebra to **manipulate** them into
595 factored form. The **Expand()** function was then able to take the factored
596 expression $(x+20)(x+4)$ and manipulate it until it was expanded. One way to
597 remember what the functions **Factor()** and **Expand()** do is to look at the second
598 letters of their names. The '**a**' in **Factor** can be thought of as **adding**
599 parentheses to an expression and the '**x**' in **Expand** can be thought of **xing** out
600 or removing parentheses from an expression.

601 **5.4.1.2 Variable And Function Names Are Case Sensitive**

602 MathPiper variables are **case sensitive**. This means that MathPiper takes into
603 account the **case** of each letter in a variable name when it is deciding if two or
604 more variable names are the same variable or not. For example, the variable
605 name **Box** and the variable name **box** are not the same variable because the first
606 variable name starts with an upper case 'B' and the second variable name starts
607 with a lower case 'b':

```
608 In> Box := 1
609 Result> 1
```

```
610 In> box := 2
611 Result> 2
```

```
612 In> Box
613 Result> 1
```

```
614 In> box
615 Result> 2
```

616 **5.4.1.3 Using More Than One Variable**

617 Programs are able to have more than 1 variable and here is a more sophisticated
618 example which uses 3 variables:

```
619 a := 2
620 Result> 2
```

```
621 b := 3
622 Result> 3
```

```
623 a + b
624 Result> 5
```

```
625 answer := a + b
626 Result> 5
```

```
627 answer
628 Result> 5
```

629 The part of an expression that is on the **right side** of an assignment operator is
630 always evaluated first and the result is then assigned to the variable that is on
631 the **left side** of the operator.

632 Now that you have seen how to use the MathPiper console as both a **symbolic**

633 and a **numeric** calculator, our next step is to take a closer look at the functions
634 which are included with MathPiper. As you will soon discover, MathPiper
635 contains an amazing number of functions which deal with a wide range of
636 mathematics.

637 **5.5 Exercises**

638 Use the MathPiper console which is at the bottom of the MathRider application
639 to complete the following exercises.

640 **5.5.1 Exercise 1**

641 Perform the following calculation:

$$\frac{1}{4} + \frac{3}{8} - \frac{7}{16}$$

642 **5.5.2 Exercise 2**

643 a) Assign the variable **ans** to the result of the calculation $\frac{1}{5} + \frac{7}{4} + \frac{15}{16}$ using
644 the following line of code:

645 In> ans := 1/5 + 7/4 + 15/16

646 b) Use the Numerator() function to calculate the numerator of ans.

647 c) Use the Denominator() function to calculate the denominator of ans.

648 d) Use the N() function to calculate the numeric value of ans.

649 e) Use the Clear() function to unbind the variable ans and verify that ans
650 is unbound by executing the following code and by using the IsBound()
651 function:

652 In> ans

653 **5.5.3 Exercise 3**

654 Assign $\frac{1}{4}$ to variable **x**, $\frac{3}{8}$ to variable **y**, and $\frac{7}{16}$ to variable **z** using the
655 := operator. Then perform the following calculations:

656 a)

657 In> x

658 b)

659 In> y

```
660 c)
661 In> z

662 d)
663 In> x + y

664 d)
665 In> x + z

666 e)
667 In> x + y + z
```

6 The MathPiper Documentation Plugin

MathPiper has a significant amount of reference documentation written for it and this documentation has been placed into a plugin called **MathPiperDocs** in order to make it easier to navigate. The MathPiperDocs plugin is available in a tab called "MathPiperDocs" which is near the right side of the MathRider application. Click on this tab to open the plugin and click on it again to close it.

The left side of the MathPiperDocs window contains the names of all the functions that come with MathPiper and the right side of the window contains a mini-browser that can be used to navigate the documentation.

6.1 Function List

MathPiper's functions are divided into two main categories called **user** functions and **programmer functions**. In general, the **user functions** are used for solving problems in the MathPiper console or with short programs and the **programmer functions** are used for longer programs. However, users will often use some of the programmer functions and programmers will use the user functions as needed.

Both the user and programmer function names have been placed into a "tree" on the left side of the MathPiperDocs window to allow for easy navigation. The branches of the function tree can be opened and closed by clicking on the small "circle with a line attached to it" symbol which is to the left of each branch. Both the user and programmer branches have the functions they contain organized into categories and the **top category in each branch** lists all the functions in the branch in **alphabetical order** for quick access. Clicking on a function will bring up documentation about it in the browser window and selecting the **Collapse** button at the top of the plugin will collapse the tree.

Don't be intimidated by the large number of categories and functions that are in the function tree! Most MathRider beginners will not know what most of them mean, and some will not know what any of them mean. Part of the benefit Mathrider provides is exposing the user to the existence of these categories and functions. The more you use MathRider, the more you will learn about these categories and functions and someday you may even get to the point where you understand all of them. This book is designed to show newbies how to begin using these functions using a gentle step-by-step approach.

6.2 Mini Web Browser Interface

MathPiper's reference documentation is in HTML (or web page) format and so the right side of the plugin contains a mini web browser that can be used to navigate through these pages. The browser's **home page** contains links to the main parts of the MathPiper documentation. As links are selected, the **Back** and

706 **Forward** buttons in the upper right corner of the plugin allow the user to move
707 backward and forward through previously visited pages and the **Home** button
708 navigates back to the home page.

709 The function names in the function tree all point to sections in the HTML
710 documentation so the user can access function information either by navigating
711 to it with the browser or jumping directly to it with the function tree.

712 **6.3 Exercises**

713 **6.3.1 Exercise 1**

714 Locate the `N()`, `IsEven()`, `IsOdd()`, `Clear()`, `IsBound()`, `Numerator()`,
715 `Denominator()`, and `Factor()` functions in the **All Functions** section of the
716 MathPiperDocs plugin and read the information that is available on them.

717 **6.3.2 Exercise 2**

718 Locate the `N()`, `IsEven()`, `IsOdd()`, `Clear()`, `IsBound()`, `Numerator()`,
719 `Denominator()`, and `Factor()` functions in the **User Functions** section of the
720 MathPiperDocs plugin and list which section each function is contained in.
721 Don't include the **Alphabetical** or **Built In** subsections in your search.

722 **7 Using MathRider As A Programmer's Text Editor**

723 We have covered some of MathRider's mathematics capabilities and this section
724 discusses some of its programming capabilities. As indicated in a previous
725 section, MathRider is built on top of a programmer's text editor but what wasn't
726 discussed was what an amazing and powerful tool a programmer's text editor is.

727 Computer programmers are among the most intelligent and productive people in
728 the world and most of their work is done using a programmer's text editor (or
729 something similar to one). Programmers have designed programmer's text
730 editors to be super-tools which can help them maximize their personal
731 productivity and these tools have all kinds of capabilities that most people would
732 not even suspect they contained.

733 Even though this book only covers a small part of the editing capabilities that
734 MathRider has, what is covered will enable the user to begin writing useful
735 programs.

736 **7.1 Creating, Opening, Saving, And Closing Text Files**

737 A good way to begin learning how to use MathRider's text editing capabilities is
738 by creating, opening, and saving text files. A text file can be created either by
739 selecting **File->New** from the menu bar or by selecting the icon for this
740 operation on the tool bar. When a new file is created, an empty text area is
741 created for it along with a new tab named **Untitled**.

742 The file can be saved by selecting **File->Save** from the menu bar or by selecting
743 the **Save** icon in the tool bar. The first time a file is saved, MathRider will ask
744 the user what it should be named and it will also provide a file system navigation
745 window to determine where it should be placed. After the file has been named
746 and saved, its name will be shown in the tab that previously displayed **Untitled**.

747 A file can be closed by selecting **File->Close** from the menu bar and it can be
748 opened by selecting **File->Open**.

749 **7.2 Editing Files**

750 If you know how to use a word processor, then it should be fairly easy for you to
751 learn how to use MathRider as a text editor. Text can be selected by dragging
752 the mouse pointer across it and it can be cut or copied by using actions in the
753 **Edit** menu (or by using **<Ctrl>x** and **<Ctrl>c**). Pasting text can be done using
754 the Edit menu actions or by pressing **<Ctrl>v**.

755 **7.3 File Modes**

756 Text file names are suppose to have a file extension which indicates what type of

757 file it is. For example, test.**txt** is a generic text file, test.**bat** is a Windows batch
758 file, and test.**sh** is a Unix/Linux shell script (**unfortunately, Windows is usually**
759 **configured to hide file extensions, but viewing a file's properties by right-clicking**
760 **on it will show this information.**).

761 MathRider uses a file's extension type to set its text area into a customized
762 **mode** which highlights various parts of its contents. For example, MathRider
763 worksheet files have a **.mrw** extension and MathRider knows what colors to
764 highlight the various parts of a .mrw file in.

765 ***7.4 Learning How To Type Properly Is An Excellent Investment Of Your*** 766 ***Time***

767 This is a good place in the document to mention that learning how to type
768 properly is an investment that will pay back dividends throughout your whole
769 life. Almost any work you do on a computer (including programming) will be
770 done *much* faster and with less errors if you know how to type properly. Here is
771 what Steve Yegge has to say about this subject:

772 "If you are a programmer, or an IT professional working with computers in *any*
773 capacity, **you need to learn to type!** I don't know how to put it any more clearly
774 than that."

775 A good way to learn how to program is to locate a free "learn how to type"
776 program on the web and use it.

777 ***7.5 Exercises***

778 ***7.5.1 Exercise 1***

779 Create a text file called "**my_text_file.txt**" and place a few sentences in
780 it. Save the text file somewhere on your hard drive then close it. Now,
781 open the text file again using **File->Open** and verify that what you typed is
782 still in the file.

783 8 MathRider Worksheet Files

784 While MathRider's ability to execute code inside a console provides a significant
785 amount of power to the user, most of MathRider's power is derived from
786 **worksheets**. MathRider worksheets are text files which have a **.mrw** extension
787 and are able to execute multiple types of code in a single text area. The
788 **worksheet_demo_1.mrw** file (which is preloaded in the MathRider environment
789 when it is first launched) demonstrates how a worksheet is able to execute
790 multiple types of code in what are called **code folds**.

791 8.1 Code Folds

792 Code folds are named sections inside a MathRider worksheet which contain
793 source code that can be executed by placing the cursor inside of it and pressing
794 **<shift><Enter>**. A fold always begins with a **start tag**, which starts with a
795 percent symbol (%) followed by the **name of the fold type** (like this:
796 **%<foldtype>**). The end of a fold is marked by an **end tag** which looks like
797 **%/<foldtype>**. The only difference between a fold's start tag and its end tag is
798 that the end tag has a slash (/) after the %.

799 For example, here is a MathPiper fold which will print the result of **2 + 3** to the
800 MathPiper console (**Note: the semicolon ';' which is at the end of the line of**
801 **code is required**):

```
802 %mathpiper
803 2 + 3;
804 %/mathpiper
```

805 The **output** generated by a fold (called the **parent fold**) is wrapped in a **new**
806 **fold** (called a **child fold**) which is indented and placed just below the parent.
807 This can be seen when the above fold is executed by pressing **<shift><enter>**
808 inside of it:

```
809 %mathpiper
810 2 + 3;
811 %/mathpiper
812     %output,preserve="false"
813     Result: 5
814 .    %/output
```

815 The most common type of output fold is **%output** and by default folds of type

816 %output have their **preserve property** set to **false**. This tells MathRider to
817 overwrite the %output fold with a new version during the next execution of its
818 parent. If preserve is set to **true**, the fold will not be overwritten and a new fold
819 will be created instead.

820 There are other kinds of child folds, but in the rest of this document they will all
821 be referred to in general as "output" folds.

822 8.1.1 The Description Attribute

823 Folds can also have what is called a "**description attribute**" placed after the
824 start tag which describes what the fold contains. For example, the following
825 %mathpiper fold has a description attribute which indicates that the fold adds
826 two number together:

```
827 %mathpiper,title="Add two numbers together."
```

```
828 2 + 3;
```

```
829 %/mathpiper
```

830 The description attribute is added to the start tag of a fold by placing a comma
831 after the fold's type name and then adding the text **title="<text>"** after the
832 comma. (**Note: no spaces can be present before or after the comma (,) or**
833 **the equals sign (=)**).

834 8.2 Automatically Inserting Folds & Removing Unpreserved Folds

835 Typing the the top and bottom fold lines (for example:

```
836 %mathpiper
```

```
837 %/mathpiper
```

838 can be tedious and MathRider has a way to automatically insert them. Place the
839 cursor at the beginning of a blank line in a .mrw worksheet file where you would
840 like a fold inserted and then **press the right mouse button**.

841 A popup menu will be displayed and at the top of this menu are items which read
842 "**Insert MathPiper Fold**", "**Insert Group Fold**", etc. If you select one of these
843 menu items, an empty code fold of the proper type will automatically be inserted
844 into the .mrw file at the position of the cursor.

845 This popup menu also has a menu item called "**Remove Unpreserved Folds**". If
846 this menu item is selected, all folds which have a "**preserve="false"**" property
847 will be removed.

848 **8.3 Exercises**

849 A MathRider worksheet file called "**newbies_book_examples_1.mrw**" can be
850 obtained from this website:

851 [https://mathrider.dev.java.net/source/browse/mathrider/trunk/src/doc/newbies_bo](https://mathrider.dev.java.net/source/browse/mathrider/trunk/src/doc/newbies_book/examples/proposed/misc/newbies_book_examples_1.mrw)
852 [ok/examples/proposed/misc/newbies_book_examples_1.mrw](https://mathrider.dev.java.net/source/browse/mathrider/trunk/src/doc/newbies_book/examples/proposed/misc/newbies_book_examples_1.mrw)

853 It contains a number of %mathpiper folds which contain code examples from the
854 previous sections of this book. Notice that all of the lines of code have a
855 semicolon (;) placed after them. The reason this is needed is explained in a later
856 section.

857 Download this worksheet file to your computer from the section on this website
858 that contains the highest revision number and then open it in MathRider. Then,
859 use the worksheet to do the following exercises.

860 **8.3.1 Exercise 1**

861 Execute folds 1-8 in the top section of the worksheet by placing the cursor
862 inside of the fold and then pressing <shift><enter> on the keyboard.

863 **8.3.2 Exercise 2**

864 The code in folds 9 and 10 have errors in them. Fix the errors and then
865 execute the folds again.

866 **8.3.3 Exercise 3**

867 Use the empty fold 11 to calculate the expression $100 - 23$;

868 **8.3.4 Exercise 4**

869 Perform the following calculations by creating new folds at the bottom of
870 the worksheet (using the right-click popup menu) and placing each
871 calculation into its own fold:

872 a) $2 * 7 + 3$

873 b) $18 / 3$

874 c) $234238342 + 2038408203$

875 d) $324802984 * 2308098234$

876 e) Factor the result which was calculated in d).

877 9 MathPiper Programming Fundamentals

878 The MathPiper language consists of **expressions** and an expression consists of
879 one or more **symbols** which represent **values**, **operators**, **variables**, and
880 **functions**. In this section expressions are explained along with the values,
881 operators, variables, and functions they consist of.

882 9.1 Values and Expressions

883 A **value** is a single symbol or a group of symbols which represent an idea. For
884 example, the value:

885 3

886 represents the number three, the value:

887 0.5

888 represents the number one half, and the value:

889 "Mathematics is powerful!"

890 represents an English sentence.

891 Expressions can be created by using **values** and **operators** as building blocks.
892 The following are examples of simple expressions which have been created this
893 way:

894 3

895 2 + 3

896 5 + 6*21/18 - 2^3

897 In MathPiper, **expressions** can be **evaluated** which means that they can be
898 transformed into a **result value** by predefined rules. For example, when the
899 expression 2 + 3 is evaluated, the result value that is produced is 5:

900 In> 2 + 3

901 Result> 5

902 9.2 Operators

903 In the above expressions, the characters +, -, *, /, ^ are called **operators** and
904 their purpose is to tell MathPiper what **operations** to perform on the **values** in
905 an **expression**. For example, in the expression 2 + 3, the **addition** operator +
906 tells MathPiper to add the integer 2 to the integer 3 and return the result.

907 The **subtraction** operator is -, the **multiplication** operator is *, / is the
908 **division** operator, % is the **remainder** operator (which is also used as the

909 "result of the last calculation" symbol), and ^ is the **exponent** operator.
910 MathPiper has more operators in addition to these and some of them will be
911 covered later.

912 The following examples show the -, *, /, %, and ^ operators being used:

913 In> 5 - 2
914 Result> 3

915 In> 3*4
916 Result> 12

917 In> 30/3
918 Result> 10

919 In> 8%5
920 Result> 3

921 In> 2^3
922 Result> 8

923 The - character can also be used to indicate a negative number:

924 In> -3
925 Result> -3

926 Subtracting a negative number results in a positive number (Note: there must be
927 a space between the two negative signs):

928 In> - -3
929 Result> 3

930 In MathPiper, **operators** are symbols (or groups of symbols) which are
931 implemented with **functions**. One can either call the function that an operator
932 represents directly or use the operator to call the function indirectly. However,
933 using operators requires less typing and they often make a program easier to
934 read.

935 **9.3 Operator Precedence**

936 When expressions contain more than one operator, MathPiper uses a set of rules
937 called **operator precedence** to determine the order in which the operators are
938 applied to the values in the expression. Operator precedence is also referred to
939 as the **order of operations**. Operators with higher precedence are evaluated
940 before operators with lower precedence. The following table shows a subset of
941 MathPiper's operator precedence rules with higher precedence operators being
942 placed higher in the table:

943 [^] Exponents are evaluated right to left.
 944 *,%,/ Then multiplication, remainder, and division operations are evaluated
 945 left to right.
 946 +, - Finally, addition and subtraction are evaluated left to right.

947 Lets manually apply these precedence rules to the multi-operator expression we
 948 used earlier. Here is the expression in source code form:

949 5 + 6*21/18 - 2^3

950 And here it is in traditional form:

$$5 + 6 * \frac{21}{18} - 2^3$$

951 According to the precedence rules, this is the order in which MathPiper
 952 evaluates the operations in this expression:

953 5 + 6*21/18 - 2[^]3
 954 5 + 6*21/18 - 8
 955 5 + 126/18 - 8
 956 5 + 7 - 8
 957 12 - 8
 958 4

959 Starting with the first expression, MathPiper evaluates the [^] operator first which
 960 results in the 8 in the expression below it. In the second expression, the *
 961 operator is executed next, and so on. The last expression shows that the final
 962 result after all of the operators have been evaluated is 4.

963 **9.4 Changing The Order Of Operations In An Expression**

964 The default order of operations for an expression can be changed by grouping
 965 various parts of the expression within parentheses (). Parentheses force the
 966 code that is placed inside of them to be evaluated before any other operators are
 967 evaluated. For example, the expression 2 + 4*5 evaluates to 22 using the
 968 default precedence rules:

969 In> 2 + 4*5
 970 Result> 22

971 If parentheses are placed around 4 + 5, however, the addition operator is forced
 972 to be evaluated before the multiplication operator and the result is 30:

```
973 In> (2 + 4)*5
974 Result> 30
```

975 Parentheses can also be nested and nested parentheses are evaluated from the
976 most deeply nested parentheses outward:

```
977 In> ((2 + 4)*3)*5
978 Result> 90
```

979 (Note: precedence adjusting parentheses are different from the parentheses that
980 are used to call functions.)

981 Since parentheses are evaluated before any other operators, they are placed at
982 the top of the precedence table:

- 983 () Parentheses are evaluated from the inside out.
- 984 ^ Then exponents are evaluated right to left.
- 985 *,%/, Then multiplication, remainder, and division operations are evaluated
986 left to right.
- 987 +, - Finally, addition and subtraction are evaluated left to right.

988 9.5 Functions & Function Names

989 In programming, **functions** are named blocks of code that can be executed one
990 or more times by being **called** from other parts of the same program or called
991 from other programs. Functions **can have values passed to them** from the
992 calling code and they **always return a value** back to the calling code when they
993 are finished executing. An example of a function is the **IsEven()** function which
994 was discussed in an previous section.

995 Functions are one way that MathPiper enables code to be reused. Most
996 programming languages allow code to be reused in this way, although in other
997 languages these named blocks of code are sometimes called **subroutines**,
998 **procedures**, or **methods**.

999 The functions that come with MathPiper have names which consist of either a
1000 single word (such as **Sum()**) or multiple words that have been put together to
1001 form a compound word (such as **IsBound()**). All letters in the names of
1002 functions which come with MathPiper are lower case except the beginning letter
1003 in each word, which are upper case.

1004 **9.6 Functions That Produce Side Effects**

1005 Most functions are executed to obtain the **results** they produce but some
1006 functions are executed in order to **have them perform work that is not in the**
1007 **form of a result**. Functions that perform work that is not in the form of a result
1008 are said to produce **side effects**. Side effects include many forms of work such
1009 as sending information to the user, opening files, and changing values in the
1010 computer's memory.

1011 When a function produces a side effect which sends information to the user, this
1012 information has the words **Side Effects:** placed before it in the output instead of
1013 the word **Result:**. The **Echo()** and **Write()** functions are examples of functions
1014 that produce side effects and they are covered in the next section.

1015 **9.6.1 Printing Related Functions: Echo(), Write(), And Newline()**

1016 The printing related functions send text information to the user and this is
1017 usually referred to as "printing" in this document. However, it may also be called
1018 "echoing" and "writing".

1019 **9.6.1.1 Echo()**

1020 The **Echo()** function takes one expression (or multiple expressions separated by
1021 commas) evaluates each expression, and then prints the results as side effect
1022 output. The following examples illustrate this:

```
1023 In> Echo(1)
1024 Result> True
1025 Side Effects>
1026 1
```

1027 In this example, the number 1 was passed to the Echo() function, the number
1028 was evaluated (all numbers evaluate to themselves), and the result of the
1029 evaluation was then printed as a side effect. Notice that Echo() **also returned a**
1030 **result**. In MathPiper, all functions return a result, but functions whose main
1031 purpose is to produce a side effect usually just return a result of **True** if the side
1032 effect succeeded or **False** if it failed. In this case, Echo() returned a result of
1033 **True** because it was able to successfully print a 1 as its side effect.

1034 The next example shows multiple expressions being sent to Echo() (notice that
1035 the expressions are separated by commas):

```
1036 In> Echo(1,1+2,2*3)
1037 Result> True
1038 Side Effects>
1039 1 3 6
```

1040 The expressions were each evaluated and their results were returned (separated
1041 by spaces) as side effect output. If it is desired that commas be printed between
1042 the numbers in the output, simply place three commas between the expressions
1043 that are passed to Echo():

```
1044 In> Echo(1,,,1+2,,,2*3)
1045 Result> True
1046 Side Effects>
1047 1 , 3 , 6
```

1048 Each time an Echo() function is executed, it always forces the display to drop
1049 down to the next line after it is finished. This can be seen in the following
1050 program which is similar to the previous one except it uses a separate Echo()
1051 function to display each expression:

```
1052 %mathpiper
1053 Echo(1);
1054 Echo(1+2);
1055 Echo(2*3);
1056 %/mathpiper
1057 %output,preserve="false"
1058 Result: True
1059
1060 Side Effects:
1061 1
1062 3
1063 6
1064 . %/output
```

1065 Notice how the 1, the 3, and the 6 are each on their own line.

1066 Now that we have seen how Echo() works, lets use it to do something useful. If
1067 more than one expression is evaluated in a %mathpiper fold, only the result from
1068 the last expression that was evaluated (which is usually the bottommost
1069 expression) is displayed:

```
1070 %mathpiper
1071 a := 1;
1072 b := 2;
1073 c := 3;
1074 %/mathpiper
```

```
1075     %output,preserve="false"
1076     Result: 3
1077 .    %/output
```

1078 In MathPiper, programs are executed one line at a time, starting at the topmost
1079 line of code and working downwards from there. In this example, the line `a := 1;`
1080 is executed first, then the line `b := 2;` is executed, and so on. Notice, however,
1081 that even though we wanted to see what was in all three variables, only the
1082 content of the last variable was displayed.

1083 The following example shows how `Echo()` can be used to display the contents of
1084 all three variables:

```
1085 %mathpiper
1086 a := 1;
1087 Echo(a);
1088 b := 2;
1089 Echo(b);
1090 c := 3;
1091 Echo(c);
1092 %/mathpiper
1093     %output,preserve="false"
1094     Result: True
1095
1096     Side Effects:
1097     1
1098     2
1099     3
1100 .    %/output
```

1101 9.6.1.2 Echo Statements Are Useful For "Debugging" Programs

1102 The errors that are in a program are often called "bugs". This name came from
1103 the days when computers were the size of large rooms and were made using
1104 electromechanical parts. Periodically, bugs would crawl into the machines and
1105 interfere with its moving mechanical parts and this would cause the machine to
1106 malfunction. The bugs needed to be located and removed before the machine
1107 would run properly again.

1108 Of course, even back then most program errors were produced by programmers
1109 entering wrong programs or entering programs wrong, but they liked to say that
1110 all of the errors were caused by bugs and not by themselves! The process of
1111 fixing errors in a program became known as **debugging** and the names "bugs"

1112 and "debugging" are still used by programmers today.

1113 One of the standard ways to locate bugs in a program is to place **Echo()** function
1114 calls in the code at strategic places which **print the contents of variables and**
1115 **display messages**. These Echo() functions will enable you to see what your
1116 program is doing while it is running. After you have found and fixed the bugs in
1117 your program, you can remove the debugging Echo() function calls or comment
1118 them out if you think they may be needed later.

1119 **9.6.1.3 Write()**

1120 The **Write()** function is similar to the Echo() function except it does not
1121 automatically drop the display down to the next line after it finishes executing:

```
1122 %mathpiper
1123 Write(1);
1124 Write(1+2);
1125 Echo(2*3);
1126 %/mathpiper
1127     %output,preserve="false"
1128     Result: True
1129
1130     Side Effects:
1131     1 3 6
1132 .    %/output
```

1133 Write() and Echo() have other differences besides the one discussed here and
1134 more information about them can be found in the documentation for these
1135 functions.

1136 **9.6.1.4 NewLine()**

1137 The **NewLine()** function simply prints a blank line in the side effects output. It
1138 is useful for placing vertical space between printed lines:

```
1139 %mathpiper
1140 a := 1;
1141 Echo(a);
1142 NewLine();
1143 b := 2;
1144 Echo(b);
```

```
1145 NewLine();
1146 c := 3;
1147 Echo(c);

1148 %/mathpiper

1149 %output,preserve="false"
1150 Result: True
1151
1152 Side Effects:
1153 1
1154 2
1155 3
1156 . %/output
```

1157 9.7 Expressions Are Separated By Semicolons

1158 As discussed earlier, all of the expressions that are inside of a **%mathpiper** fold
1159 must have a semicolon (;) after them. However, the expressions executed in the
1160 **MathPiper console** did not have a semicolon after them. MathPiper actually
1161 requires that all expressions end with a semicolon, but one does not need to add
1162 a semicolon to an expression which is typed into the MathPiper console **because**
1163 **the console adds it automatically** when the expression is executed.

1164 9.7.1 Placing More Than One Expression On A Line In A Fold

1165 All the previous code examples have had each of their expressions on a separate
1166 line, but multiple expressions can also be placed on a single line because the
1167 semicolons tell MathPiper where one expression ends and the next one begins:

```
1168 %mathpiper

1169 a := 1; Echo(a); b := 2; Echo(b); c := 3; Echo(c);

1170 %/mathpiper

1171 %output,preserve="false"
1172 Result: True
1173
1174 Side Effects:
1175 1
1176 2
1177 3
1178 . %/output
```

1179 The spaces that are in the code of this example are used to make the code more
1180 readable. Any spaces that are present within any expressions or between them
1181 are ignored by MathPiper and if we remove the spaces from the previous code,
1182 the output remains the same:

```
1183 %mathpiper
1184 a:=1;Echo(a);b:=2;Echo(b);c:= 3;Echo(c);
1185 %/mathpiper
1186     %output,preserve="false"
1187     Result: True
1188
1189     Side Effects:
1190     1
1191     2
1192     3
1193 .    %/output
```

1194 9.7.2 Placing More Than One Expression On A Line In The Console Using 1195 A Code Block

1196 The MathPiper console is only able to execute one expression at a time so if the
1197 previous code that executes three variable assignments and three Echo()
1198 functions on a single line is evaluated in the console, only the expression **a := 1**
1199 is executed:

```
1200 In> a := 1; Echo(a); b := 2; Echo(b); c := 3; Echo(c);
1201 Result> 1
```

1202 Fortunately, this limitation can be overcome by placing the code into a **code**
1203 **block**. A **code block** (which is also called a **compound expression**) consists of
1204 one or more expressions which are separated by semicolons and placed within an
1205 open bracket (**[**) and close bracket (**]**) pair. If a code block is evaluated in the
1206 MathPiper console, each expression in the block will be executed from left to
1207 right. The following example shows the previous code being executed within of a
1208 code block inside the MathPiper console:

```
1209 In> [a := 1; Echo(a); b := 2; Echo(b); c := 3; Echo(c);]
1210 Result> True
1211 Side Effects>
1212 1
1213 2
1214 3
```

1215 Notice that this time all of the expressions were executed and 1-3 was printed as

1216 a side effect. Code blocks always return the result of the last expression
1217 executed as the result of the whole block. In this case, True was returned as the
1218 result because the last Echo(c) function returned True. If we place another
1219 expression after the Echo(c) function, however, the block will execute this new
1220 expression last and its result will be the one returned by the block:

```
1221 In> [a := 1; Echo(a); b := 2; Echo(b); c := 3; Echo(c); 2 + 2]
1222 Result> 4
1223 Side Effects>
1224 1
1225 2
1226 3
```

1227 Finally, code blocks can have their contents placed on separate lines if desired:

```
1228 %mathpiper
1229 [
1230     a := 1;
1231
1232     Echo(a);
1233
1234     b := 2;
1235
1236     Echo(b);
1237
1238     c := 3;
1239
1240     Echo(c);
1241 ];
1242 %/mathpiper
1243
1244     %output,preserve="false"
1245     Result: True
1246
1247     Side Effects:
1248     1
1249     2
1250     3
1251 .    %/output
```

1251 Code blocks are very powerful and we will be discussing them further in later
1252 sections.

1253 9.7.2.1 Automatic Bracket, Parentheses, And Brace Match Indicating

1254 In programming, most open brackets '[' have a close bracket ']', most open
1255 parentheses '(' have a close parentheses ')', and most open braces '{' have a
1256 close brace '}'. It is often difficult to make sure that each "open" character has a

1257 matching "close" character and if any of these characters don't have a match,
1258 then an error will be produced.

1259 Thankfully, most programming text editors have a character match indicating
1260 tool that will help locate problems. To try this tool, paste the following code into
1261 a .mrw file and following the directions that are present in its comments:

```
1262 %mathpiper
1263 /*
1264     Copy this code into a .mrw file. Then, place the cursor
1265     to the immediate right of any {, }, [, ], (, or ) character.
1266     You should notice that the match to this character is
1267     indicated by a rectangle being drawing around it.
1268 */
```

```
1269 list := {1,2,3};
1270 [
1271     Echo("Hello");
1272     Echo(list);
1273 ];
```

```
1274 %/mathpiper
```

1275 9.8 Strings

1276 A **string** is a **value** that is used to hold text-based information. The typical
1277 expression that is used to create a string consists of **text which is enclosed**
1278 **within double quotes**. Strings can be assigned to variables just like numbers
1279 can and strings can also be displayed using the Echo() function. The following
1280 program assigns a string value to the variable 'a' and then echos it to the user:

```
1281 %mathpiper
1282 a := "Hello, I am a string.";
1283 Echo(a);
1284 %/mathpiper
1285 %output,preserve="false"
1286 Result: True
1287
1288 Side Effects:
1289 Hello, I am a string.
1290 . %/output
```

1291 9.8.1 The MathPiper Console and MathPiper Folds Can Access The Same 1292 Variables

1293 A useful aspect of using MathPiper inside of MathRider is that variables that are
1294 assigned inside of a **%mathpiper fold** are accessible inside of the **MathPiper**
1295 **console** and variables that are assigned inside of the **MathPiper console** are
1296 available inside of **%mathpiper folds**. For example, after the above fold is
1297 executed, the string that has been bound to variable 'a' can be displayed in the
1298 MathPiper console:

```
1299 In> a  
1300 Result> "Hello, I am a string."
```

1301 9.8.2 Using Strings To Make Echo's Output Easier To Read

1302 When the Echo() function is used to print the values of multiple variables, it is
1303 often helpful to print some information next to each variable so that it is easier to
1304 determine which value came from which Echo() function in the code. The
1305 following program prints the name of the variable that each value came from
1306 next to it in the side effects output:

```
1307 %mathpiper  
1308 a := 1;  
1309 Echo("Variable a: ", a);  
  
1310 b := 2;  
1311 Echo("Variable b: ", b);  
  
1312 c := 3;  
1313 Echo("Variable c: ", c);  
  
1314 %/mathpiper  
  
1315 %output,preserve="false"  
1316 Result: True  
1317  
1318 Side Effects:  
1319 Variable a: 1  
1320 Variable b: 2  
1321 Variable c: 3  
1322 . %/output
```

1323 9.8.2.1 Combining Strings With The : Operator

1324 If you need to combine two or more strings into one string, you can use the :
1325 operator like this:

```
1326 In> "A" : "B" : "C"
1327 Result: "ABC"
```

```
1328 In> "Hello " : "there!"
1329 Result: "Hello there!"
```

1330 **9.8.2.2 WriteString()**

1331 The **WriteString()** function prints a string without shows the double quotes that
1332 are around it.. For example, here is the Write() function being used to print the
1333 string "Hello":

```
1334 In> Write("Hello")
1335 Result: True
1336 Side Effects:
1337 "Hello"
```

1338 Notice the double quotes? Here is how the WriteString() function prints "Hello":

```
1339 In> WriteString("Hello")
1340 Result: True
1341 Side Effects:
1342 Hello
```

1343 **9.8.2.3 NI()**

1344 The **NI()** (New Line) function is used with the : function to place newline
1345 characters inside of strings:

```
1346 In> WriteString("A": NI() : "B")
1347 Result: True
1348 Side Effects:
1349 A
1350 B
```

1351 **9.8.2.4 Space()**

1352 The Space() function is used to add spaces to printed output:

```
1353 In> WriteString("A"); Space(10); WriteString("B")
1354 Result: True
1355 Side Effects:
1356 A          B
```

1357 **9.8.3 Accessing The Individual Letters In A String**

1358 Individual letters in a string (which are also called **characters**) can be accessed

1359 by placing the character's position number (also called an **index**) inside of
1360 brackets **[]** after the variable it is bound to. A character's position is determined
1361 by its distance from the left side of the string starting at 1. For example, in the
1362 string "Hello", 'H' is at position 1, 'e' is at position 2, etc. The following code
1363 shows individual characters in the above string being accessed:

```
1364 In> a := "Hello, I am a string."  
1365 Result> "Hello, I am a string."
```

```
1366 In> a[1]  
1367 Result> "H"
```

```
1368 In> a[2]  
1369 Result> "e"
```

```
1370 In> a[3]  
1371 Result> "l"
```

```
1372 In> a[4]  
1373 Result> "l"
```

```
1374 In> a[5]  
1375 Result> "o"
```

1376 9.9 Comments

1377 Source code can often be difficult to understand and therefore all programming
1378 languages provide the ability for **comments** to be included in the code.
1379 Comments are used to explain what the code near them is doing and they are
1380 usually meant to be read by humans instead of being processed by a computer.
1381 Therefore, comments are ignored by the computer when a program is executed.

1382 There are two ways that MathPiper allows comments to be added to source code.
1383 The first way is by placing two forward slashes **//** to the left of any text that is
1384 meant to serve as a comment. The text from the slashes to the end of the line
1385 the slashes are on will be treated as a comment. Here is a program that contains
1386 comments which use slashes:

```
1387 %mathpiper  
1388 //This is a comment.
```

```
1389 x := 2; //Set the variable x equal to 2.
```

```
1390 %/mathpiper
```

```
1391     %output,preserve="false"  
1392     Result: 2
```

```
1393 .    %/output
```

1394 When this program is executed, any text that starts with slashes is ignored.

1395 The second way to add comments to a MathPiper program is by enclosing the
1396 comments inside of slash-asterisk/asterisk-slash symbols `/* */`. This option is
1397 useful when a comment is too large to fit on one line. Any text between these
1398 symbols is ignored by the computer. This program shows a longer comment
1399 which has been placed between these symbols:

```
1400 %mathpiper
```

```
1401 /*  
1402  This is a longer comment and it uses  
1403  more than one line. The following  
1404  code assigns the number 3 to variable  
1405  x and then returns it as a result.  
1406  */
```

```
1407 x := 3;
```

```
1408 %/mathpiper
```

```
1409     %output,preserve="false"  
1410     Result: 3  
1411 .    %/output
```

1412 **9.10 Exercises**

1413 For the following exercises, create a new MathRider worksheet file called
1414 **section_9_exercises_<your first name>_<your last name>.mrw**. (**Note:**
1415 **there are no spaces in this file name**). For example, John Smith's worksheet
1416 would be called:

1417 **section_9_exercises_john_smith.mrw**.

1418 After this worksheet has been created, place your answer for each exercise into
1419 its own fold in this worksheet. Place a description attribute in the start tag of
1420 each fold which indicates the exercise the fold contains the solution to. The folds
1421 you create should look similar to this one:

```
1422 %mathpiper,title="Exercise 1"
```

```
1423 //Sample fold.
```

```
1424 %/mathpiper
```

1425 9.10.1 Exercise 1

1426 Change the precedence of the following expression using parentheses so that
1427 it prints 20 instead of 14:

1428 `2 + 3 * 4`

1429 9.10.2 Exercise 2

1430 Place the following calculations into a fold and then use one Echo()
1431 function per variable to print the results of the calculations. Put
1432 strings in the Echo() functions which indicate which variable each
1433 calculated value is bound to:

1434 `a := 1+2+3+4+5;`
1435 `b := 1-2-3-4-5;`
1436 `c := 1*2*3*4*5;`
1437 `d := 1/2/3/4/5;`

1438 9.10.3 Exercise 3

1439 Place the following calculations into a fold and then use one Echo()
1440 function to print the results of all the calculations on a single line
1441 (Remember, the Echo() function can print multiple values if they are
1442 separated by commas.):

1443 `Clear(x);`
1444 `a := 2*2*2*2*2;`
1445 `b := 2^5;`
1446 `c := x^2 * x^3;`
1447 `d := 2^2 * 2^3;`

1448 9.10.4 Exercise 4

1449 The following code assigns a string which contains all of the upper case
1450 letters of the alphabet to the variable **upper**. Each of the three Echo()
1451 functions prints an index number and the letter that is at that position in
1452 the string. Place this code into a fold and then continue the Echo()
1453 functions so that all 26 letters and their index numbers are printed

1454 `upper := "ABCDEFGHIJKLMNOPQRSTUVWXYZ";`

1455 `Echo(1,upper[1]);`
1456 `Echo(2,upper[2]);`
1457 `Echo(3,upper[3]);`

1458 9.10.5 Exercise 5

1459 Use Echo() functions to print an index number and the character at this
1460 position for the following string (this is similar to what was done in
1461 Exercise 4.):

```
1462 extra := "!.@#$%^&*() _+<>,?/{ }[]|\-=";
```

```
1463 Echo(1,extra[1]);
```

```
1464 Echo(2,extra[2]);
```

```
1465 Echo(3,extra[3]);
```

1466 9.10.6 Exercise 6

1467 The following program uses strings and index numbers to print a person's
1468 name. Create a program which uses the three strings from this program to
1469 print the names of three of your favorite movie actors.

```
1470 %mathpiper
```

```
1471 /*
```

```
1472     This program uses strings and index numbers to print
```

```
1473     a person's name.
```

```
1474 */
```

```
1475 upper := "ABCDEFGHJKLMNOPQRSTUVWXYZ";
```

```
1476 lower := "abcdefghijklmnopqrstuvwxyz";
```

```
1477 extra := "!.@#$%^&*() _+<>,?/{ }[]|\-=";
```

```
1478 //Print "Mary Smith."
```

```
1479 Echo(upper[13],lower[1],lower[18],lower[25],extra[12],upper[19],lower[13],l
```

```
1480 ower[9],lower[20],lower[8],extra[1]);
```

```
1481 %/mathpiper
```

```
1482     %output,preserve="false"
```

```
1483     Result: True
```

```
1484
```

```
1485     Side Effects:
```

```
1486     Mary Smith.
```

```
1487 .    %/output
```

10 Rectangular Selection Mode And Text Area Splitting

10.1 Rectangular Selection Mode

One capability that MathRider has that a word processor may not have is the ability to select rectangular sections of text. To see how this works, do the following:

- 1) Type three or four lines of text into a text area.
- 2) Hold down the **<Alt>** key then slowly press the **backslash key** (\) a few times. The bottom of the MathRider window contains a text field which MathRider uses to communicate information to the user. As **<Alt>** is repeatedly pressed, messages are displayed which read **Rectangular selection is on** and **Rectangular selection is off**.
- 3) Turn rectangular selection on and then select some text in order to see how this is different than normal selection mode. **When you are done experimenting, set rectangular selection mode to off.**

Most of the time normal selection mode is what you want to use but in certain situations rectangular selection mode is better.

10.2 Text area splitting

Sometimes it is useful to have two or more text areas open for a single document or multiple documents so that different parts of the documents can be edited at the same time. A situation where this would have been helpful was in the previous section where the output from an exercise in a MathRider worksheet contained a list of index numbers and letters which was useful for completing a later exercise.

MathRider has this ability and it is called **splitting**. If you look just to the right of the toolbar there is an icon which looks like a blank window, an icon to the right of it which looks like a window which was split horizontally, and an icon to the right of the horizontal one which is split vertically. If you let your mouse hover over these icons, a short description will be displayed for each of them. **(For now, ignore the icon which has a yellow sunburst on it. It is the New View icon and it is an advanced feature.)**

Select a text area and then experiment with splitting it by pressing the horizontal and vertical splitting buttons. Move around these split text areas with their scroll bars and when you want to unsplit the document, just press the **"Unsplit All"** icon.

11 Working With Random Integers

It is often useful to use random integers in a program. For example, a program may need to simulate the rolling of dice in a game. In this section, a function for obtaining nonnegative integers is discussed along with how to use it to simulate the rolling of dice.

11.1 Obtaining Random Integers With The `RandomInteger()` Function

One way that a MathPiper program can generate random integers is with the **`RandomInteger()`** function. The `RandomInteger()` function takes an integer as a parameter and it returns a random integer between 1 and the passed in integer. The following example shows random integers between 1 and 5 **inclusive** being obtained from `RandomInteger()`. **Inclusive** here means that both 1 and 5 are included in the range of random integers that may be returned. If the word **exclusive** was used instead, this would mean that neither 1 nor 5 would be in the range.

```
In> RandomInteger(5)
Result> 4
In> RandomInteger(5)
Result> 5
In> RandomInteger(5)
Result> 4
In> RandomInteger(5)
Result> 2
In> RandomInteger(5)
Result> 3
In> RandomInteger(5)
Result> 5
In> RandomInteger(5)
Result> 2
In> RandomInteger(5)
Result> 2
In> RandomInteger(5)
Result> 1
In> RandomInteger(5)
Result> 2
```

Random integers between 1 and 100 can be generated by passing 100 to `RandomInteger()`:

```
In> RandomInteger(100)
Result> 15
In> RandomInteger(100)
Result> 14
```

```
1562 In> RandomInteger(100)
1563 Result> 82
1564 In> RandomInteger(100)
1565 Result> 93
1566 In> RandomInteger(100)
1567 Result> 32
```

1568 A range of random integers that does not start with 1 can also be generated by
1569 using the **two argument** version of **RandomInteger()**. For example, random
1570 integers between 25 and 75 can be obtained by passing RandomInteger() the
1571 lowest integer in the range and the highest one:

```
1572 In> RandomInteger(25, 75)
1573 Result: 28
1574 In> RandomInteger(25, 75)
1575 Result: 37
1576 In> RandomInteger(25, 75)
1577 Result: 58
1578 In> RandomInteger(25, 75)
1579 Result: 50
1580 In> RandomInteger(25, 75)
1581 Result: 70
```

1582 **11.2 Simulating The Rolling Of Dice**

1583 The following example shows the simulated rolling of a single six sided die using
1584 the RandomInteger() function:

```
1585 In> RandomInteger(6)
1586 Result> 5
1587 In> RandomInteger(6)
1588 Result> 6
1589 In> RandomInteger(6)
1590 Result> 3
1591 In> RandomInteger(6)
1592 Result> 2
1593 In> RandomInteger(6)
1594 Result> 5
```

1595 Code that simulates the rolling of two 6 sided dice can be evaluated in the
1596 MathPiper console by placing it within a **code block**. The following code
1597 outputs the sum of the two simulated dice:

```
1598 In> [a := RandomInteger(6); b := RandomInteger(6); a + b;]
1599 Result> 6
1600 In> [a := RandomInteger(6); b := RandomInteger(6); a + b;]
1601 Result> 12
1602 In> [a := RandomInteger(6); b := RandomInteger(6); a + b;]
1603 Result> 6
```

```
1604 In> [a := RandomInteger(6); b := RandomInteger(6); a + b;]
1605 Result> 4
1606 In> [a := RandomInteger(6); b := RandomInteger(6); a + b;]
1607 Result> 3
1608 In> [a := RandomInteger(6); b := RandomInteger(6); a + b;]
1609 Result> 8
```

1610 Now that we have the ability to simulate the rolling of two 6 sided dice, it would
1611 be interesting to determine if some sums of these dice occur more frequently
1612 than other sums. What we would like to do is to roll these simulated dice
1613 hundreds (or even thousands) of times and then analyze the sums that were
1614 produced. We don't have the programming capability to easily do this yet, but
1615 after we finish the section on **while loops**, we will.

12 Making Decisions

The simple programs that have been discussed up to this point show some of the power that software makes available to programmers. However, these programs are limited in their problem solving ability because they are unable to make decisions. This section shows how programs which have the ability to make decisions are able to solve a wider range of problems than programs that can't make decisions.

12.1 Conditional Operators

A program's decision making ability is based on a set of special operators which are called **conditional operators**. A **conditional operator** is an operator that is used to **compare two values**. Expressions that contain conditional operators return a **boolean value** and a **boolean value** is one that can only be **True** or **False**. In case you are curious about the strange name, boolean values come from the area of mathematics called **boolean logic**. This logic was created by a mathematician named **George Boole** and this is where the name boolean came from. Table 2 shows the conditional operators that MathPiper uses:

Operator	Description
<code>x = y</code>	Returns True if the two values are equal and False if they are not equal. Notice that <code>=</code> performs a comparison and not an assignment like <code>:=</code> does.
<code>x != y</code>	Returns True if the values are not equal and False if they are equal.
<code>x < y</code>	Returns True if the left value is less than the right value and False if the left value is not less than the right value.
<code>x <= y</code>	Returns True if the left value is less than or equal to the right value and False if the left value is not less than or equal to the right value.
<code>x > y</code>	Returns True if the left value is greater than the right value and False if the left value is not greater than the right value.
<code>x >= y</code>	Returns True if the left value is greater than or equal to the right value and False if the left value is not greater than or equal to the right value.

Table 2: Conditional Operators

This example shows some of these conditional operators being evaluated in the MathPiper console:

```
In> 1 < 2
Result> True
```

```
1636 In> 4 > 5
1637 Result> False
```

```
1638 In> 8 >= 8
1639 Result> True
```

```
1640 In> 5 <= 10
1641 Result> True
```

1642 The following examples show each of the conditional operators in Table 2 being
1643 used to compare values that have been assigned to variables **x** and **y**:

```
1644 %mathpiper
```

```
1645 // Example 1.
1646 x := 2;
1647 y := 3;
```

```
1648 Echo(x, "=", y, ":", x = y);
1649 Echo(x, "!= ", y, ":", x != y);
1650 Echo(x, "< ", y, ":", x < y);
1651 Echo(x, "<= ", y, ":", x <= y);
1652 Echo(x, "> ", y, ":", x > y);
1653 Echo(x, ">= ", y, ":", x >= y);
```

```
1654 %/mathpiper
```

```
1655     %output,preserve="false"
1656     Result: True
1657
1658     Side Effects:
1659     2 = 3 :False
1660     2 != 3 :True
1661     2 < 3 :True
1662     2 <= 3 :True
1663     2 > 3 :False
1664     2 >= 3 :False
1665 .    %/output
```

```
1666 %mathpiper
```

```
1667 // Example 2.
1668 x := 2;
1669 y := 2;
```

```
1670 Echo(x, "=", y, ":", x = y);
1671 Echo(x, "!= ", y, ":", x != y);
1672 Echo(x, "< ", y, ":", x < y);
1673 Echo(x, "<= ", y, ":", x <= y);
1674 Echo(x, "> ", y, ":", x > y);
```

```
1675     Echo(x, ">= ", y, ":", x >= y);
```

```
1676 %/mathpiper
```

```
1677     %output,preserve="false"
```

```
1678     Result: True
```

```
1679
```

```
1680     Side Effects:
```

```
1681     2 = 2 :True
```

```
1682     2 != 2 :False
```

```
1683     2 < 2 :False
```

```
1684     2 <= 2 :True
```

```
1685     2 > 2 :False
```

```
1686     2 >= 2 :True
```

```
1687 .    %/output
```

```
1688 %mathpiper
```

```
1689 // Example 3.
```

```
1690 x := 3;
```

```
1691 y := 2;
```

```
1692 Echo(x, "=", y, ":", x = y);
```

```
1693 Echo(x, "!= ", y, ":", x != y);
```

```
1694 Echo(x, "< ", y, ":", x < y);
```

```
1695 Echo(x, "<= ", y, ":", x <= y);
```

```
1696 Echo(x, "> ", y, ":", x > y);
```

```
1697 Echo(x, ">= ", y, ":", x >= y);
```

```
1698 %/mathpiper
```

```
1699     %output,preserve="false"
```

```
1700     Result: True
```

```
1701
```

```
1702     Side Effects:
```

```
1703     3 = 2 :False
```

```
1704     3 != 2 :True
```

```
1705     3 < 2 :False
```

```
1706     3 <= 2 :False
```

```
1707     3 > 2 :True
```

```
1708     3 >= 2 :True
```

```
1709 .    %/output
```

```
1710 Conditional operators are placed at a lower level of precedence than the other
1711 operators we have covered to this point:
```

```
1712     ()    Parentheses are evaluated from the inside out.
```

```
1713     ^    Then exponents are evaluated right to left.
```

1714 *,%,/ Then multiplication, remainder, and division operations are evaluated
1715 left to right.

1716 +, - Then addition and subtraction are evaluated left to right.

1717 =,!=,<,<=,>,>= Finally, conditional operators are evaluated.

1718 **12.2 Predicate Expressions**

1719 Expressions which return either **True** or **False** are called "**predicate**"
1720 expressions. By themselves, predicate expressions are not very useful and they
1721 only become so when they are used with special decision making functions, like
1722 the If() function (which is discussed in the next section).

1723 **12.3 Exercises**

1724 **12.3.1 Exercise 1**

1725 Open a MathPiper session and evaluate the following predicate expressions:

1726 In> 3 = 3

1727 In> 3 = 4

1728 In> 3 < 4

1729 In> 3 != 4

1730 In> -3 < 4

1731 In> 4 >= 4

1732 In> 1/2 < 1/4

1733 In> 15/23 < 122/189

1734 /*In the following two expressions, notice that 1/2 is not considered to be
1735 equal to .5 unless it is converted to a numerical value first.*/

1736 In> 1/2 = .5

1737 In> N(1/2) = .5

1738 **12.3.2 Exercise 2**

1739 Come up with 10 predicate expressions of your own and evaluate them in the
1740 MathPiper console.

1741 **12.4 Making Decisions With The If() Function & Predicate Expressions**

1742 All programming languages have the ability to make decisions and the most
1743 commonly used function for making decisions in MathPiper is the **If()** function.

1744 There are two calling formats for the If() function:

```
If(predicate, then)  
If(predicate, then, else)
```

1745 The way the first form of the If() function works is that it evaluates the first
1746 expression in its argument list (which is the "**predicate**" expression) and then
1747 looks at the value that is returned. If this value is **True**, the "**then**" expression
1748 that is listed second in the argument list is executed. If the predicate expression
1749 evaluates to **False**, the "**then**" expression is not executed. (Note: any function
1750 that accepts a predicate expression as a parameter can also accept the boolean
1751 values True and False).

1752 The following program uses an **If()** function to determine if the value in variable
1753 number is greater than 5. If number is greater than 5, the program will echo
1754 "Greater" and then "End of program":

```
1755 %mathpiper  
1756 number := 6;  
1757 If(number > 5, Echo(number, "is greater than 5.));  
1758 Echo("End of program.");  
1759 %/mathpiper  
1760 %output,preserve="false"  
1761 Result: True  
1762  
1763 Side Effects:  
1764 6 is greater than 5.  
1765 End of program.  
1766 . %/output
```

1767 In this program, number has been set to 6 and therefore the expression number
1768 > 5 is **True**. When the **If()** function evaluates the **predicate expression** and
1769 determines it is **True**, it then executes the **first Echo()** function. The **second**
1770 **Echo()** function at the bottom of the program prints "End of program"
1771 regardless of what the If() function does. (**Note: semicolons cannot be placed**
1772 **after expressions which are in function calls.**)

1773 Here is the same program except that **number** has been set to **4** instead of **6**:

```
1774 %mathpiper
1775 number := 4;
1776 If(number > 5, Echo(number, "is greater than 5.));
1777 Echo("End of program.");
1778 %/mathpiper
1779 %output,preserve="false"
1780 Result: True
1781
1782 Side Effects:
1783 End of program.
1784 . %/output
```

1785 This time the expression **number > 4** returns a value of **False** which causes the
1786 **If()** function to not execute the "**then**" expression that was passed to it.

1787 12.4.1 If() Functions Which Include An "Else" Parameter

1788 The second form of the If() function takes a third "**else**" expression which is
1789 executed only if the predicate expression is **False**. This program is similar to the
1790 previous one except an "**else**" expression has been added to it:

```
1791 %mathpiper
1792 x := 4;
1793 If(x > 5, Echo(x, "is greater than 5."), Echo(x, "is NOT greater than 5.));
1794 Echo("End of program.");
1795 %/mathpiper
1796 %output,preserve="false"
1797 Result: True
1798
1799 Side Effects:
1800 4 is NOT greater than 5.
1801 End of program.
1802 . %/output
```

1803 **12.5 Exercises**1804 **12.5.1 Exercise 1**

1805 Write a program which uses the `RandomInteger()` function to simulate the
1806 flipping of a coin (Hint: you can use 1 to represent a head and 0 to
1807 represent a tail.). Use predicate expressions, the `If()` function, and the
1808 `Echo()` function to print the string **"The coin came up heads."** or the string
1809 **"The coin came up tails."**, depending on what the simulated coin flip came
1810 up as when the code was executed.

1811 **12.6 The `And()`, `Or()`, & `Not()` Boolean Functions & Infix Notation**1812 **12.6.1 `And()`**

1813 Sometimes a programmer needs to check if two or more expressions are all **True**
1814 and one way to do this is with the **`And()`** function. The `And()` function has **two**
1815 **calling formats** (or **notations**) and this is the first one:

```
And(expression1, expression2, expression3, ..., expressionN)
```

1816 This calling format is able to accept one or more predicate expressions as input.
1817 If **all** of these expressions returns a value of **True**, the `And()` function will also
1818 return a **True**. However, if **any** of the expressions return a **False**, then the `And()`
1819 function will return a **False**. This can be seen in the following example:

```
1820 In> And(True, True)
1821 Result> True
```

```
1822 In> And(True, False)
1823 Result> False
```

```
1824 In> And(False, True)
1825 Result> False
```

```
1826 In> And(True, True, True, True)
1827 Result> True
```

```
1828 In> And(True, True, False, True)
1829 Result> False
```

1830 The second format (or notation) that can be used to call the `And()` function is
1831 called **infix** notation:

```
expression1 And expression2
```

1832 With **infix** notation, an expression is placed on both sides of the And() function
1833 name instead of being placed inside of parentheses that are next to it:

```
1834 In> True And True
1835 Result> True
```

```
1836 In> True And False
1837 Result> False
```

```
1838 In> False And True
1839 Result> False
```

1840 Infix notation can only accept **two** expressions at a time, but it is often more
1841 convenient to use than function calling notation. The following program also
1842 demonstrates the infix version of the And() function being used:

```
1843 %mathpiper
1844 a := 7;
1845 b := 9;
1846 Echo("1: ", a < 5 And b < 10);
1847 Echo("2: ", a > 5 And b > 10);
1848 Echo("3: ", a < 5 And b > 10);
1849 Echo("4: ", a > 5 And b < 10);
1850 If(a > 5 And b < 10, Echo("These expressions are both true."));
1851 %/mathpiper
1852 %output,preserve="false"
1853 Result: True
1854
1855 Side Effects:
1856 1: False
1857 2: False
1858 3: False
1859 4: True
1860 These expressions are both true.
1861 . %/output
```

1862 12.6.2 Or()

1863 The Or() function is similar to the And() function in that it has both a function
1864 calling format and an infix calling format and it only works with predicate
1865 expressions. However, instead of requiring that all expressions be **True** in order
1866 to return a **True**, Or() will return a **True** if **one or more expressions are True**.

1867 Here is the function calling format for Or():

```
Or(expression1, expression2, expression3, ..., expressionN)
```

1868 and this example shows Or() being used with function calling format:

```
1869 In> Or(True, False)
1870 Result> True

1871 In> Or(False, True)
1872 Result> True

1873 In> Or(False, False)
1874 Result> False

1875 In> Or(False, False, False, False)
1876 Result> False

1877 In> Or(False, True, False, False)
1878 Result> True
```

1879 The infix notation format for Or() is as follows:

```
expression1 Or expression2
```

1880 and this example shows infix notation being used:

```
1881 In> True Or False
1882 Result> True

1883 In> False Or True
1884 Result> True

1885 In> False Or False
1886 Result> False
```

1887 The following program also demonstrates the infix version of the Or() function
1888 being used:

```
1889 %mathpiper

1890 a := 7;
1891 b := 9;

1892 Echo("1: ", a < 5 Or b < 10);
1893 Echo("2: ", a > 5 Or b > 10);
```

```
1894 Echo("3: ", a > 5 Or b < 10);
1895 Echo("4: ", a < 5 Or b > 10);

1896 If(a < 5 Or b < 10, Echo("At least one of these expressions is true."));

1897 %/mathpiper

1898 %output,preserve="false"
1899 Result: True
1900
1901 Side Effects:
1902 1: True
1903 2: True
1904 3: True
1905 4: False
1906 At least one of these expressions is true.
1907 . %/output
```

1908 12.6.3 Not() & Prefix Notation

1909 The **Not()** function works with predicate expressions like the And() and Or()
1910 functions do, except it can only accept **one** expression as input. The way Not()
1911 works is that it changes a **True** value to a **False** value and a **False** value to a
1912 **True** value. Here is the Not()'s function calling format:

```
Not(expression)
```

1913 and this example shows Not() being used with function calling format:

```
1914 In> Not(True)
1915 Result> False

1916 In> Not(False)
1917 Result> True
```

1918 Instead of providing an alternative infix calling format like And() and Or() do,
1919 Not()'s second calling format uses **prefix** notation:

```
Not expression
```

1920 Prefix notation looks similar to function notation except no parentheses are used:

```
1921 In> Not True
1922 Result> False
```

```
1923 In> Not False
1924 Result> True
```

1925 Finally, here is a program that also uses the prefix version of Not():

```
1926 %mathpiper
1927 Echo("3 = 3 is ", 3 = 3);
1928 Echo("Not 3 = 3 is ", Not 3 = 3);
1929 %/mathpiper
1930     %output,preserve="false"
1931     Result: True
1932
1933     Side Effects:
1934     3 = 3 is True
1935     Not 3 = 3 is False
1936 .    %/output
```

1937 **12.7 Exercises**

1938 **12.7.1 Exercise 1**

1939 The following program simulates the rolling of two dice and prints a
1940 message if **both** of the two dice come up less than or equal to 3. Create a
1941 similar program which simulates the flipping of two coins and print the
1942 message "Both coins came up heads." if both coins come up heads.

```
1943 %mathpiper
1944 /*
1945    This program simulates the rolling of two dice and prints a message if
1946    both of the two dice come up less than or equal to 3.
1947 */
1948
1948 dice1 := RandomInteger(6);
1949 dice2 := RandomInteger(6);
1950
1950 Echo("Dice1: ", dice1, " Dice2: ", dice2);
1951 NewLine();
1952
1952 If( dice1 <= 3 And dice2 <= 3, Echo("Both dice came up <= to 3.") );
1953 %/mathpiper
```

1954 **12.7.2 Exercise 2**

1955 The following program simulates the rolling of two dice and prints a

```
1956 message if either of the two dice come up less than or equal to 3. Create
1957 a similar program which simulates the flipping of two coins and print the
1958 message "At least one coin came up heads." if at least one coin comes up
1959 heads.

1960 %mathpiper
1961 /*
1962     This program simulates the rolling of two dice and prints a message if
1963     either of the two dice come up less than or equal to 3.
1964 */

1965 dice1 := RandomInteger(6);
1966 dice2 := RandomInteger(6);

1967 Echo("Dice1: ", dice1, "   Dice2: ", dice2);
1968 NewLine();

1969 If( dice1 <= 3 Or dice2 <= 3, Echo("At least one die came up <= 3.") );

1970 %/mathpiper
```

13 The While() Looping Function & Bodied Notation

Many kinds of machines, including computers, derive much of their power from the principle of **repeated cycling**. **Repeated cycling** in a MathPiper program means to execute one or more expressions over and over again and this process is called "**looping**". MathPiper provides a number of ways to implement **loops** in a program and these ways range from straight-forward to subtle.

We will begin discussing looping in MathPiper by starting with the straight-forward **While** function. The calling format for the **While** function is as follows:

```
While(predicate)
[
    body_expressions
];
```

The **While** function is similar to the **If** function except it will repeatedly execute the expressions it contains as long as its "predicate" expression is **True**. As soon as the predicate expression returns a **False**, the While() function skips the expressions it contains and execution continues with the expression that immediately follows the While() function (if there is one).

The expressions which are contained in a While() function are called its "**body**" and all functions which have body expressions are called "**bodied**" functions. If a body contains more than one expression then these expressions need to be placed within a **code block** (code blocks were discussed in an earlier section). What a function's body is will become clearer after studying some example programs.

13.1 Printing The Integers From 1 to 10

The following program uses a While() function to print the integers from 1 to 10:

```
%mathpiper

// This program prints the integers from 1 to 10.

/*
    Initialize the variable count to 1
    outside of the While "loop".
*/
count := 1;

While(count <= 10)
[
    Echo(count);
```

```
2006
2007     count := count + 1;  //Increment count by 1.
2008 1;
2009 %/mathpiper
2010     %output,preserve="false"
2011     Result: True
2012
2013     Side Effects:
2014     1
2015     2
2016     3
2017     4
2018     5
2019     6
2020     7
2021     8
2022     9
2023     10
2024 .    %/output
```

2025 In this program, a single variable called **count** is created. It is used to tell the
2026 Echo() function which integer to print and it is also used in the predicate
2027 expression that determines if the While() function should continue to **loop** or not.

2028 When the program is executed, 1 is placed into **count** and then the While()
2029 function is called. The predicate expression **count** <= 10 becomes **1** <= 10
2030 and, since 1 is indeed less than or equal to 10, a value of **True** is returned by the
2031 predicate expression.

2032 The While() function sees that the predicate expression returned a **True** and
2033 therefore it executes all of the expressions inside of its **body** from top to bottom.

2034 The Echo() function prints the current contents of count (which is 1) and then the
2035 expression count := count + 1 is executed.

2036 The expression **count := count + 1** is a standard expression form that is used in
2037 many programming languages. Each time an expression in this form is
2038 evaluated, it **increases the variable it contains by 1**. Another way to describe
2039 the effect this expression has on **count** is to say that it **increments count by 1**.

2040 In this case **count** contains **1** and, after the expression is evaluated, **count**
2041 contains **2**.

2042 After the last expression inside the body of the While() function is executed, the
2043 While() function reevaluates its predicate expression to determine whether it
2044 should continue looping or not. Since **count** is **2** at this point, the predicate
2045 expression returns **True** and the code inside the body of the While() function is
2046 executed again. This loop will be repeated until **count** is incremented to **11** and
2047 the predicate expression returns **False**.

2048 **13.2 Printing The Integers From 1 to 100**

2049 The previous program can be adjusted in a number of ways to achieve different
2050 results. For example, the following program prints the integers from 1 to 100 by
2051 changing the **10** in the predicate expression to **100**. A Write() function is used in
2052 this program so that its output is displayed on the same line until it encounters
2053 the **wrap margin** in MathRider (which can be set in Utilities -> Buffer
2054 Options...).

```
2055 %mathpiper
2056 // Print the integers from 1 to 100.
2057 count := 1;
2058 While(count <= 100)
2059 [
2060     Write(count,,);
2061     count := count + 1; //Increment count by 1.
2062 ];
2064 %/mathpiper
2065     %output,preserve="false"
2066     Result: True
2067
2068     Side Effects:
2069     1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22,23,
2070     24,25,26,27,28,29,30,31,32,33,34,35,36,37,38,39,40,41,42,43,
2071     44,45,46,47,48,49,50,51,52,53,54,55,56,57,58,59,60,61,62,63,
2072     64,65,66,67,68,69,70,71,72,73,74,75,76,77,78,79,80,81,82,83,
2073     84,85,86,87,88,89,90,91,92,93,94,95,96,97,98,99,100
2074 . %/output
```

2075 **13.3 Printing The Odd Integers From 1 To 99**

2076 The following program prints the odd integers from 1 to 99 by changing the
2077 **increment value** in the increment expression from **1** to **2**:

```
2078 %mathpiper
2079 //Print the odd integers from 1 to 99.
2080 x := 1;
2081 While(x <= 100)
2082 [
2083     Write(x,,);
```

```
2084     x := x + 2;    //Increment x by 2.
2085 ];
2086 %/mathpiper
2087     %output,preserve="false"
2088     Result: True
2089
2090     Side Effects:
2091     1, 3, 5, 7, 9, 11, 13, 15, 17, 19, 21, 23, 25, 27, 29, 31, 33, 35, 37, 39, 41, 43,
2092     45, 47, 49, 51, 53, 55, 57, 59, 61, 63, 65, 67, 69, 71, 73, 75, 77, 79, 81, 83,
2093     85, 87, 89, 91, 93, 95, 97, 99
2094 .    %/output
```

2095 **13.4 Printing The Integers From 1 To 100 In Reverse Order**

2096 Finally, the following program prints the integers from 1 to 100 in reverse order:

```
2097 %mathpiper
2098 //Print the integers from 1 to 100 in reverse order.
2099 x := 100;
2100 While(x >= 1)
2101 [
2102     Write(x, , );
2103     x := x - 1;    //Decrement x by 1.
2104 ];
2105 %/mathpiper
2106     %output,preserve="false"
2107     Result: True
2108
2109     Side Effects:
2110     100, 99, 98, 97, 96, 95, 94, 93, 92, 91, 90, 89, 88, 87, 86, 85, 84, 83, 82,
2111     81, 80, 79, 78, 77, 76, 75, 74, 73, 72, 71, 70, 69, 68, 67, 66, 65, 64, 63,
2112     62, 61, 60, 59, 58, 57, 56, 55, 54, 53, 52, 51, 50, 49, 48, 47, 46, 45, 44,
2113     43, 42, 41, 40, 39, 38, 37, 36, 35, 34, 33, 32, 31, 30, 29, 28, 27, 26, 25,
2114     24, 23, 22, 21, 20, 19, 18, 17, 16, 15, 14, 13, 12, 11, 10, 9, 8, 7, 6, 5, 4,
2115     3, 2, 1
2116 .    %/output
```

2117 In order to achieve the reverse ordering, this program had to initialize **x** to **100**,
2118 check to see if **x** was **greater than or equal to 1** ($x \geq 1$), and **decrement** **x** by
2119 **subtracting 1 from it** instead of adding 1 to it.

2120 **13.5 Expressions Inside Of Code Blocks Are Indented**

2121 In the programs in the previous sections which use while loops, notice that the
2122 expressions which are inside of the While() function's code block are **indented**.
2123 These expressions do not need to be indented to execute properly, but doing so
2124 makes the program easier to read.

2125 **13.6 Long-Running Loops, Infinite Loops, & Interrupting Execution**

2126 It is easy to create a loop that will execute a **large number of times**, or even **an**
2127 **infinite number of times**, either on purpose or by mistake. When you execute
2128 a program that contains an **infinite loop**, it will run until you tell MathPiper to
2129 **interrupt** its execution. This is done by opening the MathPiper console and then
2130 pressing the **"Stop"** button which it contains. The Stop button is circular and it
2131 has an X on it. (**Note: currently this button only works if MathPiper is**
2132 **executed inside of a %mathpiper fold.**)

2133 Lets experiment with the **Stop** button by executing a program that contains an
2134 infinite loop and then stopping it:

```
2135 %mathpiper
2136 //Infinite loop example program.
2137 x := 1;
2138 While(x < 10)
2139 [
2140     x := 3; //Oops, x is not being incremented!.
2141 ];
2142 %/mathpiper
2143     %output,preserve="false"
2144     Processing...
2145 .    %/output
```

2146 Since the contents of x is never changed inside the loop, the expression **x < 10**
2147 always evaluates to **True** which causes the loop to continue looping. Notice that
2148 the %output fold contains the word **"Processing..."** to indicate that the program
2149 is still running the code.

2150 Execute this program now and then interrupt it using the **"Stop"** button. When
2151 the program is interrupted, the %output fold will display the message **"User**
2152 **interrupted calculation"** to indicate that the program was interrupted. After a
2153 program has been interrupted, the program can be edited and then rerun.

2154 **13.7 A Program That Simulates Rolling Two Dice 50 Times**

2155 The following program is larger than the previous programs that have been
2156 discussed in this book, but it is also more interesting and more useful. It uses a
2157 While() loop to simulate the rolling of two dice 50 times and it records how many
2158 times each possible sum has been rolled so that this data can be printed. The
2159 comments in the code explain what each part of the program does. (Remember, if
2160 you copy this program to a MathRider worksheet, you can use **rectangular**
2161 **selection mode** to easily remove the line numbers).

```
2162 %mathpiper
2163 /*
2164     This program simulates rolling two dice 50 times.
2165 */

2166 /*
2167     These variables are used to record how many times
2168     a possible sum of two dice has been rolled. They are
2169     all initialized to 0 before the simulation begins.
2170 */
2171 numberOfTwosRolled := 0;
2172 numberOfThreesRolled := 0;
2173 numberOfFoursRolled := 0;
2174 numberOfFivesRolled := 0;
2175 numberOfSixesRolled := 0;
2176 numberOfSevensRolled := 0;
2177 numberOfEightsRolled := 0;
2178 numberOfNinesRolled := 0;
2179 numberOfTensRolled := 0;
2180 numberOfElevensRolled := 0;
2181 numberOfTwelvesRolled := 0;

2182 //This variable keeps track of the number of the current roll.
2183 roll := 1;

2184 Echo("These are the rolls:");

2185 /*
2186     The simulation is performed inside of this while loop. The number of
2187     times the dice will be rolled can be changed by changing the number 50
2188     which is in the While function's predicate expression.
2189 */
2190 While(roll <= 50)
2191 [
2192     //Roll the dice.
2193     die1 := RandomInteger(6);
2194     die2 := RandomInteger(6);
```

```
2195
2196
2197 //Calculate the sum of the two dice.
2198 rollSum := die1 + die2;
2199
2200
2201 /*
2202  Print the sum that was rolled.  Note: if a large number of rolls
2203  is going to be performed (say > 1000), it would be best to comment
2204  out this Write() function so that it does not put too much text
2205  into the output fold.
2206 */
2207 Write(rollSum,,);
2208
2209
2210 /*
2211  These If() functions determine which sum was rolled and then add
2212  1 to the variable which is keeping track of the number of times
2213  that sum was rolled.
2214 */
2215 If(rollSum = 2, numberOfTwosRolled := numberOfTwosRolled + 1);
2216 If(rollSum = 3, numberOfThreesRolled := numberOfThreesRolled + 1);
2217 If(rollSum = 4, numberOfFoursRolled := numberOfFoursRolled + 1);
2218 If(rollSum = 5, numberOfFivesRolled := numberOfFivesRolled + 1);
2219 If(rollSum = 6, numberOfSixesRolled := numberOfSixesRolled + 1);
2220 If(rollSum = 7, numberOfSevensRolled := numberOfSevensRolled + 1);
2221 If(rollSum = 8, numberOfEightsRolled := numberOfEightsRolled + 1);
2222 If(rollSum = 9, numberOfNinesRolled := numberOfNinesRolled + 1);
2223 If(rollSum = 10, numberOfTensRolled := numberOfTensRolled + 1);
2224 If(rollSum = 11, numberOfElevensRolled := numberOfElevensRolled+1);
2225 If(rollSum = 12, numberOfTwelvesRolled := numberOfTwelvesRolled+1);
2226
2227
2228 //Increment the roll variable to the next roll number.
2229 roll := roll + 1;
2230 ];
2231
2232 //Print the contents of the sum count variables for visual analysis.
2232 NewLine();
2233 NewLine();
2234 Echo("Number of Twos rolled: ", numberOfTwosRolled);
2235 Echo("Number of Threes rolled: ", numberOfThreesRolled);
2236 Echo("Number of Fours rolled: ", numberOfFoursRolled);
2237 Echo("Number of Fives rolled: ", numberOfFivesRolled);
2238 Echo("Number of Sixes rolled: ", numberOfSixesRolled);
2239 Echo("Number of Sevens rolled: ", numberOfSevensRolled);
2240 Echo("Number of Eights rolled: ", numberOfEightsRolled);
2241 Echo("Number of Nines rolled: ", numberOfNinesRolled);
2242 Echo("Number of Tens rolled: ", numberOfTensRolled);
2243 Echo("Number of Elevens rolled: ", numberOfElevensRolled);
2244 Echo("Number of Twelves rolled: ", numberOfTwelvesRolled);
```

```
2245  %/mathpiper
2246      %output,preserve="false"
2247      Result: True
2248
2249      Side effects:
2250      These are the rolls:
2251      4,8,6,4,6,9,7,11,9,3,11,6,11,7,11,4,7,7,8,7,3,6,7,7,7,12,4,
2252      12,7,8,12,6,8,10,10,5,9,8,4,5,3,5,7,7,4,6,7,7,5,8,
2253
2254      Number of Twos rolled: 0
2255      Number of Threes rolled: 3
2256      Number of Fours rolled: 6
2257      Number of Fives rolled: 4
2258      Number of Sixes rolled: 6
2259      Number of Sevens rolled: 13
2260      Number of Eights rolled: 6
2261      Number of Nines rolled: 3
2262      Number of Tens rolled: 2
2263      Number of Elevens rolled: 4
2264      Number of Twelves rolled: 3
2265  .  %/output
```

2266 13.8 Exercises

2267 13.8.1 Exercise 1

2268 Create a program which uses a while loop to print the even integers from 2
2269 to 50 inclusive.

2270 13.8.2 Exercise 2

2271 Create a program which prints all the multiples of 5 between 5 and 50
2272 inclusive.

2273 13.8.3 Exercise 3

2274 Create a program which simulates the flipping of a coin 500 times. Print
2275 the number of times the coin came up heads and the number of times it came
2276 up tails after the loop is finished executing.

2277 14 Predicate Functions

2278 A **predicate function** is a function that either returns **True** or **False**. Most
2279 predicate functions in MathPiper have names which begin with "**Is**". For
2280 example, **IsEven()**, **IsOdd()**, **IsInteger()**, etc. The following examples show
2281 some of the predicate functions that are in MathPiper:

```
2282 In> IsEven(4)
2283 Result> True
```

```
2284 In> IsEven(5)
2285 Result> False
```

```
2286 In> IsZero(0)
2287 Result> True
```

```
2288 In> IsZero(1)
2289 Result> False
```

```
2290 In> IsNegativeInteger(-1)
2291 Result> True
```

```
2292 In> IsNegativeInteger(1)
2293 Result> False
```

```
2294 In> IsPrime(7)
2295 Result> True
```

```
2296 In> IsPrime(100)
2297 Result> False
```

2298 There is also an **IsBound()** and an **IsUnbound()** function that can be used to
2299 determine whether or not a value is bound to a given variable:

```
2300 In> a
2301 Result> a
```

```
2302 In> IsBound(a)
2303 Result> False
```

```
2304 In> a := 1
2305 Result> 1
```

```
2306 In> IsBound(a)
2307 Result> True
```

```
2308 In> Clear(a)
2309 Result> True
```

```
2310 In> a
2311 Result> a
```

```
2312 In> IsBound(a)
2313 Result> False
```

2314 The complete list of predicate functions is contained in the **User**
2315 **Functions/Predicates** node in the MathPiperDocs plugin.

2316 **14.1 Finding Prime Numbers With A Loop**

2317 Predicate functions are very powerful when they are combined with loops
2318 because they can be used to automatically make numerous checks. The
2319 following program uses a while loop to pass the integers 1 through 20 (one at a
2320 time) to the **IsPrime()** function in order to determine which integers are prime
2321 and which integers are not prime:

```
2322 %mathpiper
2323 //Determine which numbers between 1 and 20 (inclusive) are prime.
2324 x := 1;
2325 While(x <= 20)
2326 [
2327     primeStatus := IsPrime(x);
2328     Echo(x, "is prime: ", primeStatus);
2329     x := x + 1;
2330 ];
2331
2332 %/mathpiper
2333
2334 %output,preserve="false"
2335 Result: True
2336
2337 Side Effects:
2338 1 is prime: False
2339 2 is prime: True
2340 3 is prime: True
2341 4 is prime: False
2342 5 is prime: True
2343 6 is prime: False
2344 7 is prime: True
2345 8 is prime: False
2346 9 is prime: False
2347 10 is prime: False
2348 11 is prime: True
2349 12 is prime: False
```

```
2350         13 is prime: True
2351         14 is prime: False
2352         15 is prime: False
2353         16 is prime: False
2354         17 is prime: True
2355         18 is prime: False
2356         19 is prime: True
2357         20 is prime: False
2358 .    %/output
```

2359 This program worked fairly well, but it is limited because it prints a line for each
2360 prime number and also each non-prime number. This means that if large ranges
2361 of integers were processed, enormous amounts of output would be produced.
2362 The following program solves this problem by using an If() function to only print
2363 a number if it is prime:

```
2364 %mathpiper
2365 //Print the prime numbers between 1 and 50 (inclusive).
2366 x := 1;
2367 While(x <= 50)
2368 [
2369     primeStatus := IsPrime(x);
2370
2371     If(primeStatus = True, Write(x,,) );
2372
2373     x := x + 1;
2374 ];
2375 %/mathpiper
2376 %output,preserve="false"
2377     Result: True
2378
2379     Side Effects:
2380     2,3,5,7,11,13,17,19,23,29,31,37,41,43,47,
2381 .    %/output
```

2382 This program is able to process a much larger range of numbers than the
2383 previous one without having its output fill up the text area. However, the
2384 program itself can be shortened by moving the **IsPrime()** function **inside** of the
2385 **If()** function instead of using the **primeStatus** variable to communicate with it:

```
2386 %mathpiper
2387 /*
```

```
2388     Print the prime numbers between 1 and 50 (inclusive).
2389     This is a shorter version which places the IsPrime() function
2390     inside of the If() function instead of using a variable.
2391 */
2392 x := 1;
2393 While(x <= 50)
2394 [
2395     If(IsPrime(x), Write(x,,) );
2396
2397     x := x + 1;
2398 ];
2399 %/mathpiper
2400     %output,preserve="false"
2401     Result: True
2402
2403     Side Effects:
2404     2,3,5,7,11,13,17,19,23,29,31,37,41,43,47,
2405     . %/output
```

2406 **14.2 Finding The Length Of A String With The Length() Function**

2407 Strings can contain zero or more characters and the **Length()** function can be
2408 used to determine how many characters a string holds:

```
2409 In> s := "Red"
2410 Result> "Red"
2411 In> Length(s)
2412 Result> 3
```

2413 In this example, the string "Red" is assigned to the variable **s** and then **s** is
2414 passed to the **Length()** function. The **Length()** function returned a **3** which
2415 means the string contained **3 characters**.

2416 The following example shows that strings can also be passed to functions
2417 directly:

```
2418 In> Length("Red")
2419 Result> 3
```

2420 An **empty string** is represented by **two double quote marks with no space in**
2421 **between them**. The **length** of an empty string is **0**:

```
2422 In> Length("")
2423 Result> 0
```

2424 **14.3 Converting Numbers To Strings With The String() Function**

2425 Sometimes it is useful to convert a number to a string so that the individual
2426 digits in the number can be analyzed or manipulated. The following example
2427 shows a **number** being converted to a **string** with the **String()** function so that
2428 its **leftmost** and **rightmost** digits can be placed into **variables**:

```
2429 In> number := 523
2430 Result> 523
```

```
2431 In> stringNumber := String(number)
2432 Result> "523"
```

```
2433 In> leftmostDigit := stringNumber[1]
2434 Result> "5"
```

```
2435 In> rightmostDigit := stringNumber[ Length(stringNumber) ]
2436 Result> "3"
```

2437 Notice that the Length() function is used here to determine which character in
2438 **stringNumber** held the **rightmost** digit.

2439 **14.4 Finding Prime Numbers Which End With 7 (And Multi-line Function Calls)**

2441 Now that we have covered how to turn a number into a string, lets use this
2442 ability inside a loop. The following program finds all the **prime numbers**
2443 between **1** and **500** which have a **7 as their rightmost digit**. There are three
2444 important things which are shown in this program:

2445 1) Function calls **can have their parameters placed on more than one**
2446 **line** if the parameters are too long to fit on a **single line**. In this case, a long
2447 code block is being placed inside of an If() function.

2448 2) Code blocks (which are considered to be compound expressions) **cannot**
2449 **have a semicolon placed after them if they are in a function call**. If a
2450 semicolon is placed after this code block, an error will be produced.

2451 3) If() functions can be placed inside of other If() functions in order to make
2452 more complex decisions. This is referred to as **nesting** functions.

2453 When the program is executed, it finds 24 prime numbers which have 7 as their
2454 rightmost digit:

```
2455 %mathpiper
2456 /*
2457     Find all the prime numbers between 1 and 500 which have a 7
2458     as their rightmost digit.
2459 */
2460 x := 1;
2461 While(x <= 500)
2462 [
2463     //Notice how function parameters can be put on more than one line.
2464     If(IsPrime(x),
2465         [
2466             stringVersionOfNumber := String(x);
2467             stringLength := Length(stringVersionOfNumber);
2468             //Notice that If() functions can be placed inside of other
2469             // If() functions.
2470             If(stringVersionOfNumber[stringLength] = "7", Write(x,,) );
2471         ] //Notice that semicolons cannot be placed after code blocks
2472         //which are in function calls.
2473     ); //This is the close parentheses for the outer If() function.
2474     x := x + 1;
2475 ];
2481 %/mathpiper
2482 %output,preserve="false"
2483 Result: True
2484
2485 Side Effects:
2486 7,17,37,47,67,97,107,127,137,157,167,197,227,257,277,307,317,
2487 337,347,367,397,457,467,487,
2488 . %/output
```

2489 It would be nice if we had the ability to store these numbers someplace so that
2490 they could be processed further and this is discussed in the next section.

2491 14.5 Exercises

2492 14.5.1 Exercise 1

2493 Write a program which uses a loop to determine how many prime numbers there
2494 are between 1 and 1000. You do not need to print the numbers themselves,
2495 just how many there are.

2496 14.5.2 Exercise 2

2497 Write a program which uses a loop to print all of the prime numbers between
2498 10 and 99 which contain the digit 3 in either their 1's place, or their
2499 10's place, or both places.

2500 15 Lists: Values That Hold Sequences Of Expressions

2501 The **list** value type is designed to hold expressions in an **ordered collection** or
2502 **sequence**. Lists are very flexible and they are one of the most heavily used
2503 value types in MathPiper. Lists can **hold expressions of any type**, they can be
2504 made to **grow and shrink as needed**, and they can be **nested**. Expressions in a
2505 list can be **accessed by their position** in the list (similar to the way that
2506 characters in a string are accessed) and they can also be **replaced by other**
2507 **expressions**.

2508 One way to create a list is by placing zero or more expressions separated by
2509 commas inside of a **pair of braces {}**. In the following example, a list is created
2510 that contains various expressions and then it is assigned to the variable **x**:

```
2511 In> x := {7,42,"Hello",1/2,var}  
2512 Result> {7,42,"Hello",1/2,var}
```

```
2513 In> x  
2514 Result> {7,42,"Hello",1/2,var}
```

2515 The number of expressions in a list can be determined with the **Length()**
2516 function:

```
2517 In> Length({7,42,"Hello",1/2,var})  
2518 Result> 5
```

2519 A single expression in a list can be accessed by placing a set of **brackets []** to
2520 the right of the variable that is bound to the list and then putting the
2521 expression's position number inside of the brackets (**Note: the first expression**
2522 **in the list is at position 1 counting from the left end of the list**):

```
2523 In> x[1]  
2524 Result> 7
```

```
2525 In> x[2]  
2526 Result> 42
```

```
2527 In> x[3]  
2528 Result> "Hello"
```

```
2529 In> x[4]  
2530 Result> 1/2
```

```
2531 In> x[5]  
2532 Result> var
```

2533 The **1st** and **2nd** expressions in this list are **integers**, the **3rd** expression is a

2534 **string**, the **4th** expression is a **rational number** and the **5th** expression is an
2535 **unbound variable**.

2536 Lists can also hold other lists as shown in the following example:

```
2537 In> x := {20, 30, {31, 32, 33}, 40}
```

```
2538 Result> {20,30,{31,32,33},40}
```

```
2539 In> x[1]
```

```
2540 Result> 20
```

```
2541 In> x[2]
```

```
2542 Result> 30
```

```
2543 In> x[3]
```

```
2544 Result> {31,32,33}
```

```
2545 In> x[4]
```

```
2546 Result> 40
```

```
2547
```

2548 The expression in the **3rd** position in the list is another **list** which contains the
2549 integers **31**, **32**, and **33**.

2550 An expression in this second list can be accessed by two **two sets of brackets**:

```
2551 In> x[3][2]
```

```
2552 Result> 32
```

2553 The **3** inside of the first set of brackets accesses the **3rd** member of the **first** list
2554 and the **2** inside of the second set of brackets accesses the **2nd** member of the
2555 **second** list.

2556 **15.1 Append() & Nondestructive List Operations**

```
Append(list, expression)
```

2557 The **Append()** function adds an expression to the end of a list:

```
2558 In> testList := {21,22,23}
```

```
2559 Result> {21,22,23}
```

```
2560 In> Append(testList, 24)
```

```
2561 Result> {21,22,23,24}
```

2562 However, instead of changing the **original** list, **Append()** creates a **copy** of the
2563 **original** list and appends the expression to the **copy**. This can be confirmed by
2564 evaluating the variable **testList** after the **Append()** function has been called:

```
2565 In> testList
2566 Result> {21,22,23}
```

2567 Notice that the list that is bound to **testList** was not modified by the **Append()**
2568 function. This is called a **nondestructive list operation** and **most MathPiper**
2569 **functions that manipulate lists do so nondestructively**. To have the new list
2570 bound to the variable that is being used, the following technique can be
2571 employed:

```
2572 In> testList := {21,22,23}
2573 Result> {21,22,23}

2574 In> testList := Append(testList, 24)
2575 Result> {21,22,23,24}

2576 In> testList
2577 Result> {21,22,23,24}
```

2578 After this code has been executed, the new list has indeed been bound to
2579 **testList** as desired.

2580 There are some functions, such as **DestructiveAppend()**, which **do** change the
2581 original list and most of them begin with the word "Destructive". These are
2582 called "destructive functions" and they are advanced functions which are not
2583 covered in this book.

2584 **15.2 Using While Loops With Lists**

2585 Functions that loop can be used to **select each expression in a list in turn** so
2586 that an operation can be performed on these expressions. The following
2587 program uses a while loop to print each of the expressions in a list:

```
2588 %mathpiper
2589 //Print each number in the list.

2590 x := {55,93,40,21,7,24,15,14,82};
2591 y := 1;

2592 While(y <= Length(x))
2593 [
2594     Echo(y, "- ", x[y]);
2595     y := y + 1;
2596 ];

2597 %/mathpiper

2598 %output,preserve="false"
```

```
2599         Result: True
2600
2601         Side Effects:
2602         1 - 55
2603         2 - 93
2604         3 - 40
2605         4 - 21
2606         5 - 7
2607         6 - 24
2608         7 - 15
2609         8 - 14
2610         9 - 82
2611 .    %/output
```

2612 A **loop** can also be used to search through a list. The following program uses a
2613 **While()** function and an **If()** function to search through a list to see if it contains
2614 the number **53**. If 53 is found in the list, a message is printed:

```
2615 %mathpiper
2616 //Determine if 53 is in the list.
2617 testList := {18,26,32,42,53,43,54,6,97,41};
2618 index := 1;
2619 While(index <= Length(testList))
2620 [
2621     If(testList[index] = 53,
2622         Echo("53 was found in the list at position", index));
2623     index := index + 1;
2624 ];
2625
2626 %/mathpiper
2627 %output,preserve="false"
2628     Result: True
2629
2630     Side Effects:
2631     53 was found in the list at position 5
2632 .    %/output
```

2633 When this program was executed, it determined that **53** was present in the list at
2634 position **5**.

2635 15.2.1 Using A While Loop And Append() To Place Values In A List

2636 In an earlier section it was mentioned that it would be nice if we could store a set
2637 of values for later processing and this can be done with a **while loop** and the

2638 **Append()** function. The following program creates an empty list and assigned it
2639 to the variable **primes**. The **while loop** and the **IsPrime()** function is then used
2640 to locate the prime integers between 1 and 50 and the **Append()** function is used
2641 to place them in the list. The last part of the program then prints some
2642 information about the numbers that were placed into the list:

```
2643 %mathpiper
2644 //Place the prime numbers between 1 and 50 (inclusive) into a list.
2645 //Create an empty list.
2646 primes := {};
2647 x := 1;
2648 While(x <= 50)
2649 [
2650     /*
2651         If x is prime, append it to the end of the list and then assign
2652         the new list that is created to the variable 'primes'.
2653     */
2654     If(IsPrime(x), primes := Append(primes, x ) );
2655
2656     x := x + 1;
2657 ];
2658 //Print information about the primes that were found.
2659 Echo("Primes ", primes);
2660 Echo("The number of primes in the list = ", Length(primes) );
2661 Echo("The first number in the list = ", primes[1] );
2662 %/mathpiper
2663     %output,preserve="false"
2664     Result: True
2665
2666     Side Effects:
2667     Primes {2,3,5,7,11,13,17,19,23,29,31,37,41,43,47}
2668     The number of primes in the list = 15
2669     The first number in the list = 2
2670 .    %/output
```

2671 The ability to place values into a list with a loop is very powerful and we will be
2672 using this ability throughout the rest of the book.

2673 **15.3 Exercises**

2674 **15.3.1 Exercise 1**

2675 Create a program that uses a loop and an `IsOdd()` function to analyze the
2676 following list and then print the number of odd numbers it contains.

2677 {73, 94, 80, 37, 56, 94, 40, 21, 7, 24, 15, 14, 82, 93, 32, 74, 22, 68, 65, 52, 85, 61, 46, 86, 25}

2678 **15.3.2 Exercise 2**

2679 Create a program that uses a loop and an `IsNegativeNumber()` function to
2680 copy all of the negative numbers in the following list into a new list.
2681 Use the variable **negativeNumbers** to hold the new list.

2682 {36, -29, -33, -6, 14, 7, -16, -3, -14, 37, -38, -8, -45, -21, -26, 6, 6, 38, -20, 33, 41, -
2683 4, 24, 37, 40, 29}

2684 **15.3.3 Exercise 3**

2685 Create a program that uses a loop to analyze the following list and then
2686 print the following information about it:

- 2687 1) The largest number in the list.
2688 2) The smallest number in the list.
2689 3) The sum of all the numbers in the list.

2690 {73, 94, 80, 37, 56, 94, 40, 21, 7, 24, 15, 14, 82, 93, 32, 74, 22, 68, 65, 52, 85, 61, 46, 86, 25}

2691 **15.4 The `ForEach()` Looping Function**

2692 The **`ForEach()`** function uses a **loop** to index through a list like the `While()`
2693 function does, but it is more flexible and automatic. `ForEach()` also uses bodied
2694 notation like the `While()` function and here is its calling format:

```
ForEach(variable, list) body
```

2695 **`ForEach()`** selects each expression in a list in turn, assigns it to the passed-in
2696 "variable", and then executes the expressions that are inside of "body".
2697 Therefore, body is **executed once for each expression in the list**.

2698 **15.5 Print All The Values In A List Using A `ForEach()` function**

2699 This example shows how `ForEach()` can be used to print all of the items in a list:

2700 `%mathpiper`

```
2701 //Print all values in a list.
2702 ForEach(value, {50,51,52,53,54,55,56,57,58,59})
2703 [
2704     Echo(value);
2705 ];
2706 %mathpiper
2707     %output,preserve="false"
2708     Result: True
2709
2710     Side Effects:
2711     50
2712     51
2713     52
2714     53
2715     54
2716     55
2717     56
2718     57
2719     58
2720     59
2721 . %/output
```

2722 **15.6 Calculate The Sum Of The Numbers In A List Using ForEach()**

2723 In previous examples, counting code in the form **x := x + 1** was used to count
2724 how many times a while loop was executed. The following program uses a
2725 **ForEach()** function and a line of code similar to this counter to calculate the
2726 **sum of the numbers in a list:**

```
2727 %mathpiper
2728 /*
2729     This program calculates the sum of the numbers
2730     in a list.
2731 */
2732 //This variable is used to accumulate the sum.
2733 sum := 0;
2734 ForEach(x, {1,2,3,4,5,6,7,8,9,10} )
2735 [
2736     /*
2737         Add the contents of x to the contents of sum
2738         and place the result back into sum.
2739     */
2740     sum := sum + x;
```

```
2741
2742     //Print the sum as it is being accumulated.
2743     Write(sum,,);
2744 ];
2745 NewLine(); NewLine();
2746 Echo("The sum of the numbers in the list = ", sum);
2747 %/mathpiper
2748     %output,preserve="false"
2749     Result: True
2750
2751     Side Effects:
2752     1,3,6,10,15,21,28,36,45,55,
2753
2754     The sum of the numbers in the list = 55
2755 . %/output
```

2756 In the above program, the integers **1** through **10** were manually placed into a list
2757 by typing them individually. This method is limited because only a relatively
2758 small number of integers can be placed into a list this way. The following section
2759 discusses an operator which can be used to automatically place a large number
2760 of integers into a list with very little typing.

2761 **15.7 The .. Range Operator**

```
first .. last
```

2762 A programmer often needs to create a list which contains **consecutive integers**
2763 and the **.. "range"** operator can be used to do this. The **first** integer in the list is
2764 placed before the **..** operator and the **last** integer in the list is placed after it
2765 (**Note: there must be a space immediately to the left of the .. operator**
2766 **and a space immediately to the right of it or an error will be generated.**).
2767 Here are some examples:

```
2768 In> 1 .. 10
2769 Result> {1,2,3,4,5,6,7,8,9,10}
2770 In> 10 .. 1
2771 Result> {10,9,8,7,6,5,4,3,2,1}
2772 In> 1 .. 100
2773 Result> {1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,
2774         21,22,23,24,25,26,27,28,29,30,31,32,33,34,35,36,37,
2775         38,39,40,41,42,43,44,45,46,47,48,49,50,51,52,53,54,
2776         55,56,57,58,59,60,61,62,63,64,65,66,67,68,69,70,71,
```

```
2777         72,73,74,75,76,77,78,79,80,81,82,83,84,85,86,87,88,  
2778         89,90,91,92,93,94,95,96,97,98,99,100}
```

```
2779 In> -10 .. 10  
2780 Result> {-10,-9,-8,-7,-6,-5,-4,-3,-2,-1,0,1,2,3,4,5,6,7,8,9,10}
```

2781 As these examples show, the `..` operator can generate lists of integers in
2782 ascending order and descending order. It can also generate lists that are very
2783 large and ones that contain negative integers.

2784 Remember, though, if one or both of the spaces around the `..` are omitted, an
2785 error is generated:

```
2786 In> 1..3  
2787 Result>  
2788 Error parsing expression, near token .3.
```

2789 **15.8 Using ForEach() With The Range Operator To Print The Prime** 2790 **Numbers Between 1 And 100**

2791 The following program shows how to use a **ForEach()** function instead of a
2792 **While()** function to print the prime numbers between 1 and 100. Notice that
2793 loops that are implemented with **ForEach()** often require less typing than
2794 their **While()** based equivalents:

```
2795 %mathpiper  
  
2796 /*  
2797     This program prints the prime integers between 1 and 100 using  
2798     a ForEach() function instead of a While() function. Notice that  
2799     the ForEach() version requires less typing than the While()  
2800     version.  
2801 */  
  
2802 ForEach(x, 1 .. 100)  
2803 [  
2804     If(IsPrime(x), Write(x,,) );  
2805 ];  
  
2806 %/mathpiper  
  
2807 %output,preserve="false"  
2808 Result: True  
2809  
2810 Side Effects:  
2811     2,3,5,7,11,13,17,19,23,29,31,37,41,43,47,53,59,61,67,71,  
2812     73,79,83,89,97,  
2813 . %/output
```

2814 15.8.1 Using ForEach() And The Range Operator To Place The Prime 2815 Numbers Between 1 And 50 Into A List

2816 A ForEach() function can also be used to place values in a list, just the the
2817 While() function can:

```
2818 %mathpiper
2819 /*
2820     Place the prime numbers between 1 and 50 into
2821     a list using a ForEach() function.
2822 */
2823 //Create a new list.
2824 primes := {};
2825 ForEach(number, 1 .. 50)
2826 [
2827     /*
2828         If number is prime, append it to the end of the list and
2829         then assign the new list that is created to the variable
2830         'primes'.
2831     */
2832     If(IsPrime(number), primes := Append(primes, number) );
2833 ];
2834 //Print information about the primes that were found.
2835 Echo("Primes ", primes);
2836 Echo("The number of primes in the list = ", Length(primes) );
2837 Echo("The first number in the list = ", primes[1] );
2838 %/mathpiper
2839     %output,preserve="false"
2840     Result: True
2841
2842     Side Effects:
2843     Primes {2,3,5,7,11,13,17,19,23,29,31,37,41,43,47}
2844     The number of primes in the list = 15
2845     The first number in the list = 2
2846 .    %/output
```

2847 As can be seen from the above examples, the **ForEach()** function and the **range**
2848 **operator** can do a significant amount of work with very little typing. You will
2849 discover in the next section that MathPiper has functions which are even more
2850 powerful than these two.

2851 **15.8.2 Exercises**2852 **15.8.3 Exercise 1**

2853 Create a program that uses a **ForEach()** function and an **IsOdd()** function to
2854 analyze the following list and then print the number of odd numbers it
2855 contains.

2856 {73,94,80,37,56,94,40,21,7,24,15,14,82,93,32,74,22,68,65,52,85,61,46,86,25}

2857 **15.8.4 Exercise 2**

2858 Create a program that uses a **ForEach()** function and an **IsNegativeNumber()**
2859 function to copy all of the negative numbers in the following list into a
2860 new list. Use the variable **negativeNumbers** to hold the new list.

2861 {36,-29,-33,-6,14,7,-16,-3,-14,37,-38,-8,-45,-21,-26,6,6,38,-20,33,41,-
2862 4,24,37,40,29}

2863 **15.8.5 Exercise 3**

2864 Create a program that uses a **ForEach()** function to analyze the following
2865 list and then print the following information about it:

- 2866 1) The largest number in the list.
2867 2) The smallest number in the list.
2868 3) The sum of all the numbers in the list.

2869 {73,94,80,37,56,94,40,21,7,24,15,14,82,93,32,74,22,68,65,52,85,61,46,86,25}

2870 **15.8.6 Exercise 4**

2871 Create a program that uses a **while loop** to make a list that contains **1000**
2872 **random integers** between **1** and **100** inclusive. Then, use a **ForEach()**
2873 function to determine how many integers in the list are **prime** and use an
2874 **Echo()** function to print this total.

2875 **16 Functions & Operators Which Loop Internally**

2876 Looping is such a useful capability that MathPiper has many functions which
2877 loop internally. Now that you have some experience with loops, you can use this
2878 experience to help you imagine how these functions use loops to process the
2879 information that is passed to them.

2880 **16.1 Functions & Operators Which Loop Internally To Process Lists**

2881 This section discusses a number of functions that use loops to process lists.

2882 **16.1.1 TableForm()**

```
TableForm(list)
```

2883 The **TableForm()** function prints the contents of a list in the form of a table.
2884 Each member in the list is printed on its own line and this sometimes makes the
2885 contents of the list easier to read:

```
2886 In> testList := {2,4,6,8,10,12,14,16,18,20}  
2887 Result> {2,4,6,8,10,12,14,16,18,20}
```

```
2888 In> TableForm(testList)  
2889 Result> True  
2890 Side Effects>  
2891 2  
2892 4  
2893 6  
2894 8  
2895 10  
2896 12  
2897 14  
2898 16  
2899 18  
2900 20
```

2901 **16.1.2 Contains()**

2902 The **Contains()** function searches a list to determine if it contains a given
2903 expression. If it finds the expression, it returns **True** and if it doesn't find the
2904 expression, it returns **False**. Here is the calling format for Contains():

```
Contains(list, expression)
```

2905 The following code shows Contains() being used to locate a number in a list:

```
2906 In> Contains({50,51,52,53,54,55,56,57,58,59}, 53)
2907 Result> True
```

```
2908 In> Contains({50,51,52,53,54,55,56,57,58,59}, 75)
2909 Result> False
```

2910 The **Not()** function can also be used with predicate functions like Contains() to
2911 change their results to the opposite truth value:

```
2912 In> Not Contains({50,51,52,53,54,55,56,57,58,59}, 75)
2913 Result> True
```

2914 16.1.3 Find()

```
Find(list, expression)
```

2915 The **Find()** function searches a list for the first occurrence of a given expression.
2916 If the expression is found, the **position of its first occurrence** is returned and
2917 if it is not found, **-1** is returned:

```
2918 In> Find({23, 15, 67, 98, 64}, 15)
2919 Result> 2
```

```
2920 In> Find({23, 15, 67, 98, 64}, 8)
2921 Result> -1
```

2922 16.1.4 Count()

```
Count(list, expression)
```

2923 **Count()** determines the number of times a given expression occurs in a list:

```
2924 In> testList := {a,b,b,c,c,c,d,d,d,d,e,e,e,e,e}
2925 Result> {a,b,b,c,c,c,d,d,d,d,e,e,e,e,e}
```

```
2926 In> Count(testList, c)
2927 Result> 3
```

```
2928 In> Count(testList, e)
2929 Result> 5
```

```
2930 In> Count(testList, z)
2931 Result> 0
```

2932 **16.1.5 Select()**

```
Select(predicate function, list)
```

2933 **Select()** returns a list that contains all the expressions in a list which make a
2934 given predicate function return **True**:

```
2935 In> Select("IsPositiveInteger", {46,87,59,-27,11,86,-21,-58,-86,-52})  
2936 Result> {46,87,59,11,86}
```

2937 In this example, notice that the **name** of the predicate function is passed to
2938 **Select()** in **double quotes**. There are other ways to pass a predicate function to
2939 **Select()** but these are covered in a later section.

2940 Here are some further examples which use the **Select()** function:

```
2941 In> Select("IsOdd", {16,14,82,92,33,74,99,67,65,52})  
2942 Result> {33,99,67,65}
```

```
2943 In> Select("IsEven", {16,14,82,92,33,74,99,67,65,52})  
2944 Result> {16,14,82,92,74,52}
```

```
2945 In> Select("IsPrime", 1 .. 75)  
2946 Result> {2,3,5,7,11,13,17,19,23,29,31,37,41,43,47,53,59,61,67,71,73}
```

2947 Notice how the third example uses the **..** operator to automatically generate a list
2948 of consecutive integers from 1 to 75 for the **Select()** function to analyze.

2949 **16.1.6 The Nth() Function & The [] Operator**

```
Nth(list, index)
```

2950 The **Nth()** function simply returns the expression which is at a given position in
2951 a list. This example shows the **third** expression in a list being obtained:

```
2952 In> testList := {a,b,c,d,e,f,g}  
2953 Result> {a,b,c,d,e,f,g}
```

```
2954 In> Nth(testList, 3)  
2955 Result> c
```

2956 As discussed earlier, the **[]** operator can also be used to obtain a single
2957 expression from a list:

```
2958 In> testList[3]
2959 Result> c
```

2960 The **[]** operator can even obtain a single expression directly from a list without
2961 needing to use a variable:

```
2962 In> {a,b,c,d,e,f,g}[3]
2963 Result> c
```

2964 **16.1.7 The : Prepend Operator**

```
expression : list
```

2965 The prepend operator is a colon **:** and it can be used to add an expression to the
2966 beginning of a list:

```
2967 In> testList := {b,c,d}
2968 Result> {b,c,d}

2969 In> testList := a:testList
2970 Result> {a,b,c,d}
```

2971 **16.1.8 Concat()**

```
Concat(list1, list2, ...)
```

2972 The Concat() function is short for "concatenate" which means to join together
2973 sequentially. It takes two or more lists and joins them together into a single
2974 larger list:

```
2975 In> Concat({a,b,c}, {1,2,3}, {x,y,z})
2976 Result> {a,b,c,1,2,3,x,y,z}
```

2977 **16.1.9 Insert(), Delete(), & Replace()**

```
Insert(list, index, expression)
```

```
Delete(list, index)
```

```
Replace(list, index, expression)
```

2978 **Insert()** inserts an expression into a list at a given index, **Delete()** deletes an
2979 expression from a list at a given index, and **Replace()** replaces an expression in
2980 a list at a given index with another expression:

```
2981 In> testList := {a,b,c,d,e,f,g}
2982 Result> {a,b,c,d,e,f,g}

2983 In> testList := Insert(testList, 4, 123)
2984 Result> {a,b,c,123,d,e,f,g}

2985 In> testList := Delete(testList, 4)
2986 Result> {a,b,c,d,e,f,g}

2987 In> testList := Replace(testList, 4, xxx)
2988 Result> {a,b,c,xxx,e,f,g}
```

2989 16.1.10 Take()

```
Take(list, amount)
Take(list, -amount)
Take(list, {begin_index,end_index})
```

2990 **Take()** obtains a sublist from the **beginning** of a list, the **end** of a list, or the
2991 **middle** of a list. The expressions in the list that are not taken are discarded.

2992 A **positive** integer passed to Take() indicates how many expressions should be
2993 taken from the **beginning** of a list:

```
2994 In> testList := {a,b,c,d,e,f,g}
2995 Result> {a,b,c,d,e,f,g}

2996 In> Take(testList, 3)
2997 Result> {a,b,c}
```

2998 A **negative** integer passed to Take() indicates how many expressions should be
2999 taken from the **end** of a list:

```
3000 In> Take(testList, -3)
3001 Result> {e,f,g}
```

3002 Finally, if a **two member list** is passed to Take() it indicates the **range** of
3003 expressions that should be taken from the **middle** of a list. The **first** value in the
3004 passed-in list specifies the **beginning** index of the range and the **second** value
3005 specifies its **end**:

```
3006 In> Take(testList, {3,5})
3007 Result> {c,d,e}
```

3008 **16.1.11 Drop()**

```
Drop(list, index)
Drop(list, -index)
Drop(list, {begin_index,end_index})
```

3009 **Drop()** does the opposite of Take() in that it **drops** expressions from the
3010 **beginning** of a list, the **end** of a list, or the **middle** of a list and **returns a list**
3011 **which contains the remaining expressions.**

3012 A **positive** integer passed to Drop() indicates how many expressions should be
3013 dropped from the **beginning** of a list:

```
3014 In> testList := {a,b,c,d,e,f,g}
3015 Result> {a,b,c,d,e,f,g}
```

```
3016 In> Drop(testList, 3)
3017 Result> {d,e,f,g}
```

3018 A **negative** integer passed to Drop() indicates how many expressions should be
3019 dropped from the **end** of a list:

```
3020 In> Drop(testList, -3)
3021 Result> {a,b,c,d}
```

3022 Finally, if a **two member list** is passed to Drop() it indicates the **range** of
3023 expressions that should be dropped from the **middle** of a list. The **first** value in
3024 the passed-in list specifies the **beginning** index of the range and the **second**
3025 value specifies its **end**:

```
3026 In> Drop(testList, {3,5})
3027 Result> {a,b,f,g}
```

3028 **16.1.12 FillList()**

```
FillList(expression, length)
```

3029 The FillList() function simply creates a list which is of size "length" and fills it
3030 with "length" copies of the given expression:

```
3031 In> FillList(a, 5)
3032 Result> {a,a,a,a,a}
```

```
3033 In> FillList(42,8)
3034 Result> {42,42,42,42,42,42,42,42}
```

3035 **16.1.13 RemoveDuplicates()**

```
RemoveDuplicates(list)
```

3036 **RemoveDuplicates()** removes any duplicate expressions that are contained in a
3037 list:

```
3038 In> testList := {a,a,b,c,c,b,b,a,b,c,c}
```

```
3039 Result> {a,a,b,c,c,b,b,a,b,c,c}
```

```
3040 In> RemoveDuplicates(testList)
```

```
3041 Result> {a,b,c}
```

3042 **16.1.14 Reverse()**

```
Reverse(list)
```

3043 **Reverse()** reverses the order of the expressions in a list:

```
3044 In> testList := {a,b,c,d,e,f,g,h}
```

```
3045 Result> {a,b,c,d,e,f,g,h}
```

```
3046 In> Reverse(testList)
```

```
3047 Result> {h,g,f,e,d,c,b,a}
```

3048 **16.1.15 Partition()**

```
Partition(list, partition_size)
```

3049 The **Partition()** function breaks a list into sublists of size "partition_size":

```
3050 In> testList := {a,b,c,d,e,f,g,h}
```

```
3051 Result> {a,b,c,d,e,f,g,h}
```

```
3052 In> Partition(testList, 2)
```

```
3053 Result> {{a,b},{c,d},{e,f},{g,h}}
```

3054 If the partition_size does not divide the length of the list **evenly**, the remaining
3055 elements are discarded:

```
3056 In> Partition(testList, 3)
```

```
3057 Result> {{h,b,c},{d,e,f}}
```

3058 The number of elements that Partition() will discard can be calculated by
3059 dividing the length of a list by the partition size and obtaining the **remainder**:

```
3060 In> Length(testList) % 3  
3061 Result> 2
```

3062 Remember that % is the remainder operator. It divides two integers and returns
3063 their remainder.

3064 16.1.16 Table()

```
Table(expression, variable, begin_value, end_value, step_amount)
```

3065 The Table() function creates a list of values by doing the following:

- 3066 1) Generating a sequence of values between a "begin_value" and an
3067 "end_value" with each value being incremented by the "step_amount".
- 3068 2) Placing each value in the sequence into the specified "variable", one value
3069 at a time.
- 3070 3) Evaluating the defined "expression" (which contains the defined "variable")
3071 for each value, one at a time.
- 3072 4) Placing the result of each "expression" evaluation into the result list.

3073 This example generates a list which contains the integers 1 through 10:

```
3074 In> Table(x, x, 1, 10, 1)  
3075 Result> {1,2,3,4,5,6,7,8,9,10}
```

3076 Notice that the expression in this example is simply the variable 'x' itself with no
3077 other operations performed on it.

3078 The following example is similar to the previous one except that its expression
3079 multiplies 'x' by 2:

```
3080 In> Table(x*2, x, 1, 10, 1)  
3081 Result> {2,4,6,8,10,12,14,16,18,20}
```

3082 Lists which contain decimal values can also be created by setting the
3083 "step_amount" to a decimal:

```
3084 In> Table(x, x, 0, 1, .1)  
3085 Result> {0,0.1,0.2,0.3,0.4,0.5,0.6,0.7,0.8,0.9,1}
```

3086 **16.1.17 HeapSort()**

```
HeapSort(list, compare)
```

3087 **HeapSort()** sorts the elements of **list** into the order indicated by **compare** with
3088 **compare** typically being the **less than** operator "<" or the **greater than**
3089 operator ">":

```
3090 In> HeapSort({4,7,23,53,-2,1}, "<");  
3091 Result: {-2,1,4,7,23,53}
```

```
3092 In> HeapSort({4,7,23,53,-2,1}, ">");  
3093 Result: {53,23,7,4,1,-2}
```

```
3094 In> HeapSort({1/2,3/5,7/8,5/16,3/32}, "<")  
3095 Result: {3/32,5/16,1/2,3/5,7/8}
```

```
3096 In> HeapSort({.5,3/5,.76,5/16,3/32}, "<")  
3097 Result: {3/32,5/16,.5,3/5,.76}
```

3098 **16.2 Functions That Work With Integers**

3099 This section discusses various functions which work with integers. Some of
3100 these functions also work with non-integer values and their use with non-
3101 integers is discussed in other sections.

3102 **16.2.1 RandomIntegerVector()**

```
RandomIntegerVector(length, lowest_possible, highest_possible)
```

3103 A vector is a list that does not contain other lists. **RandomIntegerVector()**
3104 creates a list of size "length" that contains random integers that are no lower
3105 than "lowest_possible" and no higher than "highest possible". The following
3106 example creates **10** random integers between **1** and **99** inclusive:

```
3107 In> RandomIntegerVector(10, 1, 99)  
3108 Result> {73,93,80,37,55,93,40,21,7,24}
```

3109 **16.2.2 Max() & Min()**

```
Max(value1, value2)  
Max(list)
```

3110 If two values are passed to **Max()**, it determines which one is larger:

```
3111 In> Max(10, 20)
```

3112 `Result> 20`

3113 If a list of values are passed to `Max()`, it finds the largest value in the list:

3114 `In> testList := RandomIntegerVector(10, 1, 99)`

3115 `Result> {73,93,80,37,55,93,40,21,7,24}`

3116 `In> Max(testList)`

3117 `Result> 93`

3118 The **Min()** function is the opposite of the `Max()` function.

```
Min(value1, value2)
Min(list)
```

3119 If two values are passed to `Min()`, it determines which one is smaller:

3120 `In> Min(10, 20)`

3121 `Result> 10`

3122 If a list of values are passed to `Min()`, it finds the smallest value in the list:

3123 `In> testList := RandomIntegerVector(10, 1, 99)`

3124 `Result> {73,93,80,37,55,93,40,21,7,24}`

3125 `In> Min(testList)`

3126 `Result> 7`

3127 **16.2.3 Div() & Mod()**

```
Div(dividend, divisor)
Mod(dividend, divisor)
```

3128 **Div()** stands for "divide" and determines the whole number of times a divisor
3129 goes into a dividend:

3130 `In> Div(7, 3)`

3131 `Result> 2`

3132 **Mod()** stands for "modulo" and it determines the remainder that results when a
3133 dividend is divided by a divisor:

3134 `In> Mod(7,3)`

3135 `Result> 1`

3136 The remainder/modulo operator **%** can also be used to calculate a remainder:

```
3137 In> 7 % 2
3138 Result> 1
```

3139 **16.2.4 Gcd()**

```
Gcd(value1, value2)
Gcd(list)
```

3140 GCD stands for Greatest Common Divisor and the **Gcd()** function determines the
3141 greatest common divisor of the values that are passed to it.

3142 If two integers are passed to Gcd(), it calculates their greatest common divisor:

```
3143 In> Gcd(21, 56)
3144 Result> 7
```

3145 If a list of integers are passed to Gcd(), it finds the greatest common divisor of all
3146 the integers in the list:

```
3147 In> Gcd({9, 66, 123})
3148 Result> 3
```

3149 **16.2.5 Lcm()**

```
Lcm(value1, value2)
Lcm(list)
```

3150 LCM stands for Least Common Multiple and the **Lcm()** function determines the
3151 least common multiple of the values that are passed to it.

3152 If two integers are passed to Lcm(), it calculates their least common multiple:

```
3153 In> Lcm(14, 8)
3154 Result> 56
```

3155 If a list of integers are passed to Lcm(), it finds the least common multiple of all
3156 the integers in the list:

```
3157 In> Lcm({3, 7, 9, 11})
3158 Result> 693
```

3159 **16.2.6 Sum()**

```
Sum(list)
```

3160 **Sum()** can find the sum of a list that is passed to it:

3161 In> testList := RandomIntegerVector(10,1,99)

3162 Result> {73,93,80,37,55,93,40,21,7,24}

3163 In> Sum(testList)

3164 Result> 523

3165 In> testList := 1 .. 10

3166 Result> {1,2,3,4,5,6,7,8,9,10}

3167 In> Sum(testList)

3168 Result> 55

3169 **16.2.7 Product()**

```
Product(list)
```

3170 This function has two calling formats, only one of which is discussed here.

3171 **Product(list)** multiplies all the expressions in a list together and returns their
3172 product:

3173 In> Product({1,2,3})

3174 Result> 6

3175 **16.3 Exercises**3176 **16.3.1 Exercise 1**

3177 Create a program that uses **RandomIntegerVector()** to create a 100 member
3178 list that contains random integers between 1 and 5 inclusive. Use **Count()**
3179 to determine how many of each digit 1-5 are in the list and then print this
3180 information. Hint: you can use the **HeapSort()** function to sort the
3181 generated list to make it easier to check if your program is counting
3182 correctly.

3183 **16.3.2 Exercise 2**

3184 Create a program that uses **RandomIntegerVector()** to create a 100 member
3185 list that contains random integers between 1 and 50 inclusive and use
3186 **Contains()** to determine if the number 25 is in the list. Print "25 was in
3187 the list." if 25 was found in the list and "25 was not in the list." if it

3188 wasn't found.

3189 **16.3.3 Exercise 3**

3190 Create a program that uses **RandomIntegerVector()** to create a 100 member
3191 list that contains random integers between 1 and 50 inclusive and use
3192 **Find()** to determine if the number 10 is in the list. Print the position of
3193 10 if it was found in the list and "10 was not in the list." if it wasn't
3194 found.

3195 **16.3.4 Exercise 4**

3196 Create a program that uses **RandomIntegerVector()** to create a 100 member
3197 list that contains random integers between 0 and 3 inclusive. Use **Select()**
3198 with the **IsNonZeroInteger()** predicate function to obtain all of the nonzero
3199 integers in this list.

3200 **16.3.5 Exercise 5**

3201 Create a program that uses **Table()** to obtain a list which contains the
3202 squares of the integers between 1 and 10 inclusive.

3203 17 Nested Loops

3204 Now that you have seen how to solve problems with single loops, it is time to
3205 discuss what can be done when a loop is placed inside of another loop. A loop
3206 that is placed **inside** of another loop it is called a **nested loop** and this nesting
3207 can be extended to numerous levels if needed. This means that loop 1 can have
3208 loop 2 placed inside of it, loop 2 can have loop 3 placed inside of it, loop 3 can
3209 have loop 4 placed inside of it, and so on.

3210 Nesting loops allows the programmer to accomplish an enormous amount of
3211 work with very little typing.

3212 17.1 Generate All The Combinations That Can Be Entered Into A Two Digit 3213 Wheel Lock Using Two Nested Loops

3214 The following program generates all the combinations that can be entered into a
3215 two digit wheel lock. It uses a nested loop to accomplish this with the "**inside**"
3216 nested loop being used to generate **one's place** digits and the "**outside**" loop
3217 being used to generate **ten's place** digits.

```
3218 %mathpiper
3219 /*
3220  Generate all the combinations can be entered into a two
3221  digit wheel lock.
3222  */
3223 combinations := {};
3224 ForEach(digit1, 0 .. 9) //This loop is called the "outside" loop.
```

```
3225 [
3226   ForEach(digit2, 0 .. 9)//This loop is called the "inside" loop.
3227   [
3228     combinations := Append(combinations, {digit1, digit2});
3229   ];
3230 ];

3231 Echo(TableForm(combinations));

3232 %/mathpiper

3233   %output,preserve="false"
3234   Result: True
3235
3236   Side Effects:
3237   {0,0}
3238   {0,1}
3239   {0,2}
3240   {0,3}
3241   {0,4}
3242   {0,5}
3243   {0,6}
3244   .
3245   . //The middle of the list has not been shown.
3246   .
3247   {9,3}
3248   {9,4}
3249   {9,5}
3250   {9,6}
3251   {9,7}
3252   {9,8}
3253   {9,9}
3254   True
3255 . %/output
```

3256 The relationship between the outside loop and the inside loop is interesting
3257 because each time the **outside loop cycles once**, the **inside loop cycles 10**
3258 **times**. Study this program carefully because nested loops can be used to solve a
3259 wide range of problems and therefore understanding how they work is
3260 important.

3261 17.2 Exercises

3262 17.2.1 Exercise 1

3263 Create a program that will generate all of the combinations that can be
3264 entered into a three digit wheel lock. (Hint: a triple nested loop can be
3265 used to accomplish this.)

3266 18 User Defined Functions

3267 In computer programming, a **function** is a named section of code that can be
3268 **called** from other sections of code. **Values** can be sent to a function for
3269 processing as part of the **call** and a function always returns a value as its result.
3270 A function can also generate side effects when it is called and side effects have
3271 been covered in earlier sections.

3272 The values that are sent to a function when it is called are called **arguments** or
3273 **actual parameters** and a function can accept 0 or more of them. These
3274 arguments are placed within parentheses.

3275 MathPiper has many predefined functions (some of which have been discussed in
3276 previous sections) but users can create their own functions too. The following
3277 program creates a function called **addNums()** which takes two numbers as
3278 arguments, adds them together, and returns their sum back to the calling code
3279 as a result:

```
3280 In> addNums(num1,num2) := num1 + num2
3281 Result> True
```

3282 This line of code defined a new function called **addNums** and specified that it
3283 will accept two values when it is called. The **first** value will be placed into the
3284 variable **num1** and the **second** value will be placed into the variable **num2**.

3285 Variables like num1 and num2 which are used in a function to accept values from
3286 calling code are called **formal parameters**. **Formal parameter variables** are
3287 used inside a function to process the **values/actual parameters/arguments**
3288 that were placed into them by the calling code.

3289 The code on the **right side** of the **assignment operator** is **bound** to the
3290 function name "**addNums**" and it is executed each time **addNums()** is called.
3291 The following example shows the new **addNums()** function being called multiple
3292 times with different values being passed to it:

```
3293 In> addNums(2,3)
3294 Result> 5
```

```
3295 In> addNums(4,5)
3296 Result> 9
```

```
3297 In> addNums(9,1)
3298 Result> 10
```

3299 Notice that, unlike the functions that come with MathPiper, we chose to have this
3300 function's name start with a **lower case letter**. We could have had addNums()
3301 begin with an upper case letter but it is a **convention** in MathPiper for **user**

3302 **defined function names to begin with a lower case letter to distinguish**
3303 **them from the functions that come with MathPiper.**

3304 The values that are returned from user defined functions can also be assigned to
3305 variables. The following example uses a %mathpiper fold to define a function
3306 called **evenIntegers()** and then this function is used in the MathPiper console:

```
3307 %mathpiper
3308 evenIntegers(endInteger) :=
3309 [
3310     resultList := {};
3311     x := 2;
3312     While(x <= endInteger)
3313     [
3314         resultList := Append(resultList, x);
3315         x := x + 2;
3316     ];
3317     /*
3318     The result of the last expression which is executed in a function
3319     is the result that the function returns to the caller. In this case,
3320     resultList is purposely being executed last so that its contents are
3321     returned to the caller.
3322     */
3323     resultList;
3324 ];
3325
3326 %/mathpiper
3327
3328 %output,preserve="false"
3329 Result: True
3330 . %/output
3331
3332 In> a := evenIntegers(10)
3333 Result> {2,4,6,8,10}
3334
3335 In> Length(a)
3336 Result> 5
```

3335 The function **evenIntegers()** returns a list which contains all the even integers
3336 from 2 up through the value that was passed into it. The fold was first executed
3337 in order to define the **evenIntegers()** function and make it ready for use. The
3338 **evenIntegers()** function was then called from the MathPiper console and 10
3339 was passed to it.

3340 After the function was finished executing, it returned a list of even integers as a

3341 result and this result was assigned to the variable 'a'. We then passed the list
3342 that was assigned to 'a' to the **Length()** function in order to determine its size.

3343 **18.1 Global Variables, Local Variables, & Local()**

3344 The new **evenIntegers()** function seems to work well, but there is a problem.
3345 The variables 'x' and **resultList** were defined inside the function as **global**
3346 **variables** which means they are accessible from anywhere, including from
3347 within other functions, within other folds (as shown here):

```
3348 %mathpiper
3349 Echo(x, ",", resultList);
3350 %/mathpiper
3351     %output,preserve="false"
3352     Result: True
3353
3354     Side Effects:
3355     12 , {2,4,6,8,10}
3356 .    %/output
```

3357 and from within the MathPiper console:

```
3358 In> x
3359 Result> 12
3360 In> resultList
3361 Result> {2,4,6,8,10}
```

3362 **Using global variables inside of functions is usually not a good idea**
3363 because code in other functions and folds might already be using (or will use) the
3364 same variable names. Global variables which have the same name are the same
3365 variable. When one section of code changes the value of a given global variable,
3366 the value is changed everywhere that variable is used and this will eventually
3367 cause problems.

3368 In order to prevent errors being caused by global variables having the same
3369 name, a function named **Local()** can be called inside of a function to define what
3370 are called **local variables**. A **local variable** is only accessible inside the
3371 function it has been defined in, even if it has the same name as a global variable.
3372 The following example shows a second version of the **evenIntegers()** function
3373 which uses **Local()** to make 'x' and **resultList** local variables:

```
3374 %mathpiper
3375 /*
3376  This version of evenIntegers() uses Local() to make
3377  x and resultList local variables
3378  */
3379 evenIntegers(endInteger) :=
3380 [
3381     Local(x,resultList);
3382     resultList := {};
3383
3384     x := 2;
3385
3386     While(x <= endInteger)
3387     [
3388         resultList := Append(resultList, x);
3389         x := x + 2;
3390     ];
3391
3392     /*
3393     The result of the last expression which is executed in a function
3394     is the result that the function returns to the caller. In this case,
3395     resultList is purposely being executed last so that its contents are
3396     returned to the caller.
3397     */
3398     resultList;
3399 ];
3400 %/mathpiper
3401     %output,preserve="false"
3402     Result: True
3403 .    %/output
```

3404 We can verify that '**x**' and **resultList** are now local variables by first clearing
3405 them, calling **evenIntegers()**, and then seeing what '**x**' and **resultList** contain:

```
3406 In> Clear(x, resultList)
3407 Result> True
3408 In> evenIntegers(10)
3409 Result> {2,4,6,8,10}
3410 In> x
3411 Result> x
3412 In> resultList
3413 Result> resultList
```

3414 **18.2 Exercises**3415 **18.2.1 Exercise 1**

3416 Create a function called **tenOddIntegers()** which returns a list which
3417 contains 10 random odd integers between 1 and 99 inclusive.

3418 **18.2.2 Exercise 2**

3419 Create a function called **convertStringToList(string)** which takes a string
3420 as a parameter and returns a list which contains all of the characters in
3421 the string. Here is an example of how the function should work:

3422 In> convertStringToList("Hello friend!")

3423 Result> {"H","e","l","l","o"," ","f","r","i","e","n","d","!"}

3424 In> convertStringToList("Computer Algebra System")

3425 Result> {"C","o","m","p","u","t","e","r"," ","A","l","g","e","b","r","a","
3426 ","S","y","s","t","e","m"}

3427 19 Miscellaneous topics

3428 19.1 Incrementing And Decrementing Variables With The ++ And -- 3429 Operators

3430 Up until this point we have been adding 1 to a variable with code in the form of **x**
3431 **:= x + 1** and subtracting 1 from a variable with code in the form of **x := x - 1**.
3432 Another name for **adding** 1 to a variable is **incrementing** it and **decrementing**
3433 a variable means to **subtract** 1 from it. Now that you have had some experience
3434 with these longer forms, it is time to show you shorter versions of them.

3435 19.1.1 Incrementing Variables With The ++ Operator

3436 The number 1 can be added to a variable by simply placing the ++ operator after
3437 it like this:

```
3438 In> x := 1  
3439 Result: 1
```

```
3440 In> x++;  
3441 Result: True
```

```
3442 In> x  
3443 Result: 2
```

3444 Here is a program that uses the ++ operator to increment a loop index variable:

```
3445 %mathpiper  
3446 count := 1;  
3447 While(count <= 10)  
3448 [  
3449     Echo(count);  
3450  
3451     count++; //The ++ operator increments the count variable.  
3452 ];  
3453 %/mathpiper  
3454 %output,preserve="false"  
3455 Result: True  
3456  
3457 Side Effects:  
3458 1  
3459 2
```

```
3460      3
3461      4
3462      5
3463      6
3464      7
3465      8
3466      9
3467     10
3468 .    %/output
```

3469 19.1.2 Decrementing Variables With The -- Operator

3470 The number 1 can be subtracted from a variable by simply placing the --
3471 operator after it like this:

```
3472 In> x := 1
3473 Result: 1

3474 In> x--;
3475 Result: True

3476 In> x
3477 Result: 0
```

3478 Here is a program that uses the -- operator to decrement a loop index variable:

```
3479 %mathpiper

3480 count := 10;

3481 While(count >= 1)
3482 [
3483     Echo(count);
3484     count--; //The -- operator decrements the count variable.
3486 ];

3487 %/mathpiper

3488 %output,preserve="false"
3489 Result: True
3490
3491 Side Effects:
3492 10
3493 9
3494 8
3495 7
3496 6
3497 5
```

```
3498         4
3499         3
3500         2
3501         1
3502     .    %/output
```
